AUSTRALIAN PRODUCT INFORMATION

BEXSERO (multicomponent meningococcal group b vaccine) suspension for injection

1 NAME OF THE MEDICINE

Multicomponent Meningococcal group B Vaccine (recombinant, adsorbed)

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

BEXSERO is a multicomponent Meningococcal group B vaccine presented as a suspension for injection in a pre-filled syringe containing purified recombinant meningococcal protein antigens expressed in E. coli and outer membrane vesicles (OMV) derived from *N. meningitidis* group B. Bactericidal antibodies directed against components of the bacterium protect against Invasive Meningococcal Disease (IMD).

1 dose (0.5 mL) of BEXSERO contains:

Neisseria meningitidis Group B Neisseria Heparin Binding Antigen fusion protein[1,2] (rbe)	- 50 micrograms
Neisseria meningitidis Group B Neisseria Adhesin A protein[1,2] (rbe)	- 50 micrograms
Neisseria meningitidis Group B Factor H Binding Protein fusion protein[1,2] (rbe)	- 50 micrograms
Outer membrane vesicles (OMV) from *Neisseria meningitidis* group B strain NZ98/254 measured as amount of total protein containing the PorA P1.4[2]	- 25 micrograms

[1] Produced in *E. coli* cells by recombinant DNA technology. The NHBA (*Neisseria* Heparin Binding Antigen) is derived from strain NZ98/254 and is fused with accessory protein 953, derived from strain 2996; NadA (*Neisseria* adhesin A) is derived from strain 2996; fHBP (factor H Binding Protein) is derived from strain MC58 and is fused with accessory protein 936, derived from strain 2996.

[2] Adsorbed on aluminium hydroxide hydrate (0.5 mg Al^{3+}).

For the full list of excipients, see Section 6.1 LIST OF EXCIPIENTS.

3 PHARMACEUTICAL FORM

White opalescent liquid suspension.

BEXSERO is supplied in a 1.0 mL (Type I glass) pre-filled syringe. Syringes are sealed with a plunger stopper (Type I bromobutyl rubber) and with a protective tip cap (Type II rubber).

4 CLINICAL PARTICULARS

4.1 THERAPEUTIC INDICATIONS

BEXSERO is indicated for active immunisation against invasive disease caused by *N. meningitidis* group B strains. For information on protection against specific group B strains See Section 5.1 PHARMACODYNAMIC PROPERTIES.

BEXSERO is indicated for vaccination of individuals from 2 months of age and older.

4.2 DOSE AND METHOD OF ADMINISTRATION

In the absence of compatibility studies, this medicinal product must not be mixed with other medicinal products. BEXSERO can be given at the same time as other immunisations, provided that the vaccine is administered either at a different site or away from the injection site of the other vaccine, according to local guidelines.

Infants 2 months to 5 months of age at the time of the first dose
The primary infant vaccination schedule consists of two or three doses, each of 0.5 ml, with an interval not less than 2 months between doses (2-dose primary schedule) or 1 month between doses (3-dose primary schedule). The first dose should be given no earlier than 2 months of age The safety and efficacy of BEXSERO in infants less than 8 weeks of age has not yet been established. No data are available. A booster dose is recommended in the second year of life, from the age of 12 months or later, with an interval of at least 6 months between the primary series and booster dose (See Section 5.1 PHARMACODYNAMIC PROPERTIES - Clinical Trials).

Infants 6 months to 11 months of age at the time of the first dose
The vaccination schedule consists of two doses, each of 0.5 mL, with an interval not less than 2 months between doses. A booster dose is recommended in the second year of life with an interval of at least 2 months between the primary series and booster dose (See Section 5.1 PHARMACODYNAMIC PROPERTIES - Clinical Trials).

Toddlers 12 months to 23 months of age at the time of the first dose
The vaccination schedule consists of two doses, each of 0.5 mL, with an interval not less than 2 months between doses. A booster dose is recommended with an interval of 12 months to 23 months between the primary series and booster dose (See Section 5.1 PHARMACODYNAMIC PROPERTIES - Clinical Trials).

Children 2 years to 10 years of age at the time of the first dose
The vaccination schedule consists of two doses, each of 0.5 mL, with an interval not less than 1 month between doses. The need for a booster dose after this vaccination schedule has not been established. A booster dose should be considered in individuals at continued risk of exposure to meningococcal disease, based on official recommendations (See Section 5.1 PHARMACODYNAMIC PROPERTIES - Clinical Trials).

Adolescents and adults from 11 years of age at the time of first dose
Two doses, each of 0.5 mL, with an interval of at least 1 month between doses. The need for a booster dose after this vaccination schedule has not been established. A booster dose

should be considered in individuals at continued risk of exposure to meningococcal disease, based on official recommendations (See Section 5.1 PHARMACODYNAMIC PROPERTIES - Clinical Trials).

The safety and efficacy of BEXSERO in individuals above 50 years of age have not been established.

Table 1: Summary of Dosages

Age at first dose	Primary Immunisation	Intervals between Primary Doses	Booster
Infants, 2 months to 5 months[a]	Two doses each of 0.5 mL	Not less than 2 months	Yes, 1 dose in the second year of life, from the age of 12 months or later, with an interval of at least 6 months between the primary series and booster dose[b]
	Three doses each of 0.5 mL	Not less than 1 month	
Infants, 6 months to 11 months	Two doses each of 0.5 mL	Not less than 2 months	Yes, 1 dose in the second year of life with an interval of at least 2 months between the primary series and booster dose[b]
Toddlers, 12 months to 23 months	Two doses each of 0.5 mL	Not less than 2 months	Yes, 1 dose with an interval of 12 months to 23 months between the primary series and booster dose[b]
Children, 2 years to 10 years	Two doses each of 0.5 mL	Not less than 1 month	Need not established[b,c]
Adolescents (from, 11 years) and adults*	Two doses each of 0.5 mL	Not less than 1 month	Need not established[b,c]

[a] The first dose should be given no earlier than 2 months of age. The safety and efficacy of BEXSERO in infants less than 8 weeks of age has not yet been established. No data are available.
[b] See Section 5.1 CLINICAL TRIALS.
[c] A booster dose should be considered in individuals at continued risk of exposure to meningococcal disease, based on official recommendations.
* The safety and efficacy of BEXSERO in individuals above 50 years of age have not been established.

Sufficient data are not available on the safety and effectiveness of using BEXSERO and other meningococcal group B vaccines interchangeably to complete the vaccination series. Therefore, it is recommended that subjects who receive a first dose of BEXSERO, complete the vaccination course with BEXSERO.

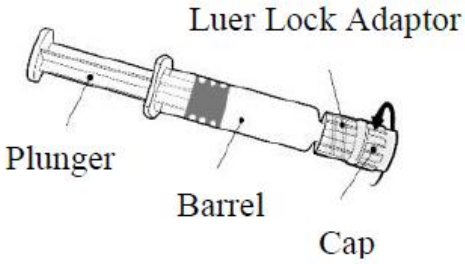
Further guidance regarding the use of vaccines can be found in the Australian Immunisation Handbook.

Method of Administration

The vaccine is given by deep intramuscular injection, preferably in the anterolateral aspect of the thigh in infants or in the deltoid muscle region of the upper arm in older subjects. Separate injection sites must be used if more than one vaccine is administered at the same time. Administer in accordance with local guidelines.

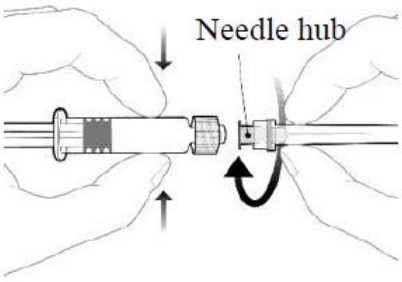
The vaccine must not be injected intravenously, subcutaneously or intradermally and must not be mixed with other vaccines in the same syringe.

Instructions for the pre-filled syringe



Hold the syringe by the barrel, not by the plunger.

Unscrew the syringe cap by twisting it anticlockwise.



To attach the needle, connect the hub to the Luer Lock Adaptor and rotate a quarter turn clockwise until you feel it lock.

Do not pull the syringe plunger out of the barrel. If it happens, do not administer the vaccine.

BEXSERO is for single use in one patient only.

Upon storage of the suspension, a fine off-white deposit may form. Shake the vaccine well before use to form a homogeneous suspension. The vaccine should be visually inspected for particulate matter and discoloration prior to administration. In the event of any foreign particulate matter and/or variation of physical aspect being observed, do not administer the vaccine.

Any unused product or waste material should be disposed of in accordance with local requirements.

4.3 CONTRAINDICATIONS

Hypersensitivity to the active substances (See Section 2 QUALITATIVE AND QUANTITATIVE COMPOSITION) or to any of the excipients (See Section 6.1 LIST OF EXCIPIENTS).

4.4 SPECIAL WARNINGS AND PRECAUTIONS FOR USE

As with other vaccines, administration of BEXSERO should be postponed in subjects suffering from an acute severe febrile illness. However, the presence of a minor infection, such as cold, should not result in the deferral of vaccination.

Do not inject intravascularly.

As with all injectable vaccines, appropriate medical treatment and supervision should always be readily available in case of an anaphylactic event following the administration of the vaccine.

Anxiety-related reactions, including vasovagal reactions (syncope), hyperventilation or stress-related reactions may occur in association with vaccination as a psychogenic response to the needle injection (See Section 4.8 ADVERSE EFFECTS (UNDESIRABLE EFFECTS)). It is important that procedures are in place to avoid injury from fainting.

As with any vaccine, vaccination with BEXSERO may not protect all vaccine recipients. BEXSERO is not expected to provide protection against all circulating meningococcal group B strains (See Section 5.1 PHARMACODYNAMIC PROPERTIES).

As with many vaccines, health care professionals should be aware that a temperature elevation may occur following vaccination of infants and toddlers. Accordingly, patients and/or their care givers should be made aware of the risks and management of fever and its sequelae. In infant study V72P13, fever ≥ 38.0°C was reported by 78%, 84% and 73% of participants after dose 1, 2 and 3, respectively, in the BEXSERO vaccine group, compared with 44%, 59% and 50% of participants receiving the routine vaccines alone. In the same study, fever ≥ 39.5°C was reported by 5%, 7% and 4% of participants after dose 1, 2 and 3, respectively, in the BEXSERO vaccine group, compared with 1%, 1% and 2% of participants receiving the routine vaccines alone. The rate of fever was decreased by the use of prophylactic antipyretics (as demonstrated in study V72P16). Prophylactic administration of antipyretics at the time of and closely after vaccination can reduce the incidence and intensity of post-vaccination febrile reactions. Antipyretic medication should be initiated according to local guidelines in infants and toddlers.

Individuals with impaired immune responsiveness, whether due to the use of immune-suppressive therapy, a genetic disorder, or other causes, may have reduced antibody response to active immunisation. Immunogenicity data are available in individuals with complement deficiencies, asplenia, or splenic dysfunction (See Section 5.1 CLINICAL TRIALS).

Individuals with certain complement deficiencies and individuals receiving treatment that inhibits terminal complement activation (for example, eculizumab) remain at increased risk of invasive disease caused by Neisseria meningitidis group B even if they develop antibodies following vaccination with BEXSERO.

Kanamycin is used in early manufacturing process and is removed during the later stages of manufacture. If present, kanamycin levels in the final vaccine are less than 0.01 micrograms

per dose. The safe use of BEXSERO in kanamycin-sensitive individuals has not been established.

Use in the elderly

The safety and efficacy of BEXSERO in individuals above 50 years of age have not been established. There are limited data in patients with chronic medical conditions.

Paediatric use

The potential risk of apnoea and the need for respiratory monitoring for 48-72 hours should be considered when administering the primary immunisation series to very premature infants (born ≤ 28 weeks of gestation) and particularly for those with a previous history of respiratory immaturity. As the benefit of vaccination is high in this group of infants, vaccination should not be withheld or delayed.

Effects on laboratory tests

No data available.

4.5 INTERACTIONS WITH OTHER MEDICINES AND OTHER FORMS OF INTERACTIONS

BEXSERO can be given concomitantly with any of the following vaccine antigens, either as monovalent or as combination vaccines: diphtheria, tetanus, acellular pertussis, *Haemophilus influenzae* type b, inactivated poliomyelitis, hepatitis B, heptavalent pneumococcal conjugate, measles, mumps, rubella, varicella, and meningococcal group A, C, W, Y conjugate.

Clinical studies demonstrated that the immune responses of the co-administered routine vaccines were unaffected by concomitant administration of BEXSERO. Inconsistent results were seen across studies for responses to inactivated poliovirus type 2 and pneumococcal conjugate serotype 6B, but these data do not suggest clinically significant interference.

The safety profiles of the co-administered vaccines were unaffected by concomitant administration of BEXSERO with the exception of more frequent occurrence of fever, tenderness at the injection site, change in eating habits and irritability. Prophylactic use of paracetamol reduces the incidence and severity of fever without affecting the immunogenicity of either BEXSERO or routine vaccines. The effect of antipyretics other than paracetamol on the immune response has not been studied.

Concomitant administration of BEXSERO with vaccines other than those mentioned above has not been studied.

When given concomitantly with other vaccines BEXSERO must be administered at separate injection sites (See Section 4.2 DOSE AND METHOD OF ADMINISTRATION).

4.6 FERTILITY, PREGNANCY AND LACTATION

Effects on fertility

There are no data on fertility in humans.

There were no effects on the mating performance or fertility of female rabbits in a reproductive and developmental toxicity study in which rabbits were intramuscularly injected with the clinical dose of BEXSERO 35, 21, and 7 days prior to mating and on gestation days 7 and 20. Male fertility has not been assessed in animals.

Use in pregnancy

(Pregnancy Category B1)
Insufficient clinical data on exposed pregnancies are available.

The potential risk for pregnant women is unknown. Nevertheless, vaccination should not be withheld when there is a clear risk of exposure to meningococcal infection.

A reproductive and developmental toxicity study has been performed in female rabbits intramuscularly injected 35, 21, and 7 days prior to mating and on gestation days 7 and 20 with the clinical dose of BEXSERO (approximately 10 times the human dose based on body weights). There was no evidence of maternal, foetal, or postnatal developmental effects due to BEXSERO. Vaccine-specific antibodies were detected in rabbit foetuses and kits.

Use in lactation

Information on the safety of the vaccine to women and their children during breast-feeding is not available. The benefit-risk ratio must be examined before making the decision to immunise during breast-feeding.

No adverse reactions were seen in vaccinated maternal rabbits or in their offspring through day 29 of lactation. BEXSERO was immunogenic in maternal animals vaccinated prior to lactation, and vaccine-specific antibodies were detected in the offspring, but antibody levels in milk were not determined.

4.7 EFFECTS ON ABILITY TO DRIVE AND USE MACHINES

The effects of this medicine on a person's ability to drive and use machines were not assessed as part of its registration.

However, some of the effects mentioned under Section 4.8 ADVERSE EFFECTS (UNDESIRABLE EFFECTS) may temporarily affect the ability to drive or use machines.

4.8 ADVERSE EFFECTS (UNDESIRABLE EFFECTS)

Adverse reactions from clinical studies with the BEXSERO are described below.

The safety of BEXSERO was evaluated in 13 studies including 9 randomised controlled clinical trials with 7802 participants (from 2 months of age) who received at least one dose of BEXSERO and in a subsequent study in 974 young adults. Among BEXSERO recipients, 5849 were infants and toddlers (less than 2 years of age), 250 were children (2 to 10 years of age) and 2677 were adolescents and adults. Of the participants who received primary infant series of BEXSERO, 3285 received a booster dose in the second year of life. Data for 988 infants and children (less than 2 years of age), 801 children (2 to 10 years of age), and 1803

adolescents and young adults (aged 10-25 years) exposed to BEXSERO in subsequent studies have additionally been evaluated.

In infants and toddlers, the most common local and systemic adverse reactions observed in clinical trials were tenderness and erythema at the injection site, fever and irritability.

In clinical studies in infants, fever occurred more frequently when BEXSERO was co-administered with routine vaccines (containing the following antigens: pneumococcal 7-valent conjugate, diphtheria, tetanus, acellular pertussis, hepatitis B, inactivated poliomyelitis and *Haemophilus influenzae* type b) than when it was given alone. Higher rates of antipyretic use were also reported for infants vaccinated with BEXSERO and routine vaccines. When BEXSERO was given alone, the frequency of fever was similar to that associated with routine infant vaccines administered during clinical trials. When fever occurred, it generally followed a predictable pattern, with the majority resolving by the day after vaccination.

In adolescents and adults, the most common local and systemic adverse reactions observed were pain at the injection site, malaise and headache.

No increase in the incidence or severity of the adverse reactions was seen with subsequent doses of the vaccination series.

Adverse reactions (following primary immunisation or booster dose) considered as being at least possibly related to vaccination have been categorised by frequency.

Frequencies are defined as follows:
Very common: (≥ 1/10)
Common: (≥ 1/100 to < 1/10)
Uncommon: (≥ 1/1,000 to < 1/100)
Rare: (≥ 1/10,000 to < 1/1,000)
Very rare: (< 1/10,000)

Within each frequency grouping, undesirable effects are presented in order of decreasing seriousness.

Infants, Toddlers, and Children (up to 10 years of age)
Metabolism and nutrition disorders
Very common: eating disorders

Nervous system disorders
Very common: sleepiness, unusual crying, headache
Uncommon: seizures (including febrile seizures)

Vascular disorders
Uncommon: pallor (rare after booster)
Rare: Kawasaki syndrome

Gastrointestinal disorders
Very common: diarrhea, vomiting (uncommon after booster)

Skin and subcutaneous tissue disorders
Very common: rash (toddlers) (uncommon after booster)
Common: rash (infants and children 2 to 10 years of age)
Uncommon: eczema
Rare: urticaria

General disorders and administration site conditions
Very common: fever (≥ 38°C), injection site tenderness (including severe injection site tenderness defined as crying when injected limb is moved), injection site erythema, injection site swelling, injection site induration, irritability
Common: fever (≥ 39.5°C)
Uncommon: fever (≥ 40°C)

Musculoskeletal and connective tissue disorders
Very common: arthralgia

Adolescents (from 11 years of age) and Adults
Nervous system disorders
Very common: headache

Gastrointestinal disorders
Very common: nausea

General disorders and administration site conditions
Very common: injection site pain (including severe injection site pain defined as unable to perform normal daily activity), injection site swelling, injection site induration, injection site erythema, malaise

Musculoskeletal and connective tissue disorders
Very common: myalgia, arthralgia

Adverse reactions from post-marketing spontaneous reports
In addition to reports in clinical trials, worldwide voluntary reports of adverse reactions received for BEXSERO since market introduction are listed below. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency.

Blood and lymphatic system disorders
Lymphadenopathy

General disorders and administration site conditions
Fever (adolescents from 11 years of age and adults)
Injection site reactions (including extensive swelling of the vaccinated limb, blisters at or around the injection site and injection site nodule which may persist for more than one month)

Immune system disorders
Allergic reactions (including anaphylactic reactions), rash

Nervous system disorders
Hypotonic-hyporesponsive episode
Syncope or vasovagal responses to injection

Skin and subcutaneous tissue disorders
Rash (adolescents from 11 years of age and adults)

Reporting suspected adverse effects
Reporting suspected adverse reactions after registration of the medicinal product is important. It allows continued monitoring of the benefit-risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions at www.tga.gov.au/reporting-problems.

4.9 OVERDOSE

Experience of overdose is limited. In the event of overdose, monitoring of vital functions and possible symptomatic treatment is recommended.

For information on the management of overdose, contact the Poisons Information Centre on 13 11 26 (Australia).

5 PHARMACOLOGICAL PROPERTIES

5.1 PHARMACODYNAMIC PROPERTIES

Pharmacotherapeutic group: Meningococcal vaccines, ATC code: J07AH09.

Mechanism of action

Immunisation with BEXSERO is intended to stimulate the production of bactericidal antibodies against the vaccine antigens (NHBA, NadA, fHBP, and PorA P1.4 (the immunodominant antigen present in the OMV component). The resultant antibodies are expected to be protective against Invasive Meningococcal Disease (IMD). As these antigens are variably expressed by different strains, meningococci that express these antigens at sufficient levels are susceptible to killing by vaccine-elicited antibodies.
The vaccine antigens present in BEXSERO are also expressed by strains belonging to meningococcal groups other than group B. Limited data suggest protection against some non-group B strains, however, the extent is not yet determined (See Section 5.1 PHARMACODYNAMIC PROPERTIES – Data generated in real-world settings).

Epidemiological Data
Invasive meningococcal disease (IMD) is an important cause of meningitis and septicaemia, which can lead to mortality (8.1% in Europe), or permanent sequelae (11 to 19%). According to the Australian Department of Health, the most common serogroups causing IMD in Australia are B, W and Y. However, trends in the incidence of meningococcal disease are hard to predict over time due to natural fluctuations in disease. According to the National Notifiable Diseases Surveillance System in 2016, the highest incidence of IMD occurs in children under 4 years of age (3.5 notifications per 100,000 population), followed by a peak in children from 15 to 19 years of age (2.5 notifications per 100,000 population).

Group B has caused prolonged outbreaks due to hypervirulent strains in New Zealand, with high incidences in infants (less than 1 year: 124 cases per 100,000), and children (1 to 4 years: 60 cases per 100,000).

Protection from meningococcal disease correlates with the presence of serum antibodies able to kill the bacteria in the presence of human complement. The potential of BEXSERO to induce antibodies able to kill diverse strains of invasive meningococcal group B bacteria was studied using a novel typing method, the Meningococcal Antigen Typing System (MATS). MATS was developed to relate antigen profiles of different strains of meningococcal group B bacteria to killing of the strains in the hSBA by pooled serum from 13 month old infants immunised at 2, 4 and 6 months of age with a booster at 12 months of age. A survey of 520 invasive meningococcal group B isolates collected between January 2007 and December 2011 from six Australian states and two territories showed that 75% (95% Confidence Interval: 61%-86%) of meningococcal group B isolates were predicted to be killed in hSBA based on their MATS vaccine antigen type.

Clinical trials

The efficacy of BEXSERO has been inferred by measuring bactericidal antibody responses to each of the vaccine antigens NadA, fHBP, NHBA and PorA P1.4, using a set of four meningococcal group B reference strains (5/99, H44/76, M10713 and NZ98/254). Bactericidal antibodies against these strains were measured by the Serum Bactericidal Assay using human serum as the source of complement (hSBA). Strain H44/76 measured bactericidal antibody directed against fHBP; strain 5/99 measured bactericidal antibody directed against NadA; strain M10713 measured bactericidal antibody directed against NHBA; and strain NZ98/254 measured bactericidal antibody directed against PorA P1.4 in the OMV vaccine component. Data are not available from all vaccine schedules using strain M10713.

<u>Data generated in real-world settings</u>

Impact of vaccination on disease incidence

In the UK, BEXSERO was introduced into the national immunisation programme (NIP) in September 2015 using a two-dose schedule in infants (at 2 and 4 months of age) followed by a booster dose (at 12 months of age). In this context, Public Health England (PHE) conducted a 3-year observational study at the national level covering the entire birth cohort.

After three years of the programme, a statistically significant reduction of 75% [Incidence Rate Ratio (IRR) 0.25 (95% CI: 0.19-0.36)] in MenB IMD cases was observed in vaccine-eligible infants, irrespective of the infants' vaccination status or predicted meningococcal group B strain coverage.

In South Australia, more than 30 000 students aged 16 through 19 years (from 91% of high schools), received two doses of Bexsero with a one- to three-month interval. In an interrupted time-series analysis, a statistically significant reduction of 71% (95% CI: 15-90) in MenB IMD cases was observed in the two years of follow-up (July 2017-June 2019).

<u>Immunogenicity</u>

The primary immunogenicity endpoint was measured as the proportion of participants with hSBA equal to or above the threshold of 1:4 against each of the meningococcal group B

reference strains. This threshold, used in early-stage clinical studies (V72P6, V72P9, V72P4, V72P5 and V72P10), is an accepted correlate of protection. Based on the intermediate precision of the validated assay a threshold of 1:5 was then set to ensure 95% certainty of a true response of 1:4. This cut-off was used to define seropositive responses in late-stage clinical studies in infants and children (V72P13, V72P12, V72P12E1, V72P13E1, V72P16, V72P13E2, V72P6E1, V72P9E1, V72_28, V72_28E1 and V72P10E1). Immunogenicity was evaluated in randomised, multicentre, clinical trials that enrolled infants, children, adolescents and adults.

Immunogenicity in infants 2 months to 5 months of age
Three dose primary schedule followed by a booster
In infant studies V72P13, V72P12 and V72P16, participants received three doses of BEXSERO either at 2, 4 and 6 or 2, 3 and 4 months of age with concomitant routine vaccines and a booster dose in their second year of life, as early as 12 months of age. Control groups received only routine childhood vaccinations. Sera were obtained before vaccination, one month after the third vaccination (Table 2) and one month after booster vaccination (Table 3).

Across these studies, baseline geometric mean titres (GMTs) against all four reference strains were uniformly low ranging from 1.02 to 3.28 in the BEXSERO groups and 1.01 to 4.08 in the controls.

One month after the third BEXSERO vaccination, bactericidal responses against the meningococcal reference strains fHPB, NadA, PorA P1.4 and NHBA antigens were high for both schedules. For NHBA antigen, the bactericidal responses were higher in infants vaccinated at the 2, 4, 6-month schedule than for those vaccinated on the 2, 3, 4-month schedule. The clinical consequence of the reduced immunogenicity of the NHBA antigen following the 2, 3, 4-month schedule is not known. Following routine childhood vaccination in the control group the mean hSBA GMTs against meningococcal reference strains remained low ranging from 1.04 to 2.24.

Table 2: Serum bactericidal antibody responses at 1 month following the third dose of BEXSERO given at 2, 3, 4 (Studies V72P12, V72P16) or 2, 4, 6 (Study V72P13) months of age

Antigen*	Response (95% CI)	Study V72P13 2, 4, 6 months	Study V72P12 2, 3, 4 months	Study V72P16 2, 3, 4 months
fHBP	% seropositive**	N=1149 100% (99-100)	N=273 99% (97-100)	N=170 100% (98-100)
	hSBA GMT***	91 (87-95)	82 (75-91)	101 (90-113)
NadA	% seropositive	N=1152 100% (99-100)	N=275 100% (99-100)	N=165 99% (97-100)
	hSBA GMT	635 (606-665)	325 (292-362)	396 (348-450)
PorA P1.4	% seropositive	N=1152 84% (82-86)	N=274 81% (76-86)	N=171 78% (71-84)
	hSBA GMT	14 (13-15)	11 (9.14-12)	10 (8.59-12)
NHBA	% seropositive	N=100 84% (75-91)	N=112 37% (28-46)	N=35 43% (26-61)

	hSBA GMT	16 (13-21)	3.24 (2.49-4.21)	3.29 (1.85-5.83)

* The following strains of group B meningococci, which were isolated from cases of invasive disease, were used to assess functional immunogenicity against each of the vaccine antigens by hSBA:

- fHBP antigen: strain 44/76
- NadA antigen: strain 5/99
- immunodominant PorA P1.4 component of OMV: strain NZ98/254
- NHBA antigen: strain M10713

** % seropositive = the percentage of participants who achieved an hSBA ≥ 1:5.

*** GMT = geometric mean titre.

Table 3 summarises antibody persistence pre-booster dose 8 months after primary vaccination at 2, 3 and 4 months of age and at 6 months after vaccination at 2,4 and 6 months of age. Table 3 also summarises an antibody response for both regimens one month after a booster dose administered at 12 months of age, and antibody persistence 12 months after the booster dose for the 2, 4 and 6 month regimen. Seroprotection rates and hSBA GMTs one month following the fourth dose at 12 months were indicative of a booster response for both regimens.

Table 3: Serum bactericidal antibody responses following a booster at 12 months of age after a primary series administered at 2, 3 and 4 (Study V72P12E1) or 2, 4 and 6 months of age (Study V72P13E1), and persistence of bactericidal antibody one year after the booster (Study V72P13E2)

* The following strains of group B meningococci, which were isolated from cases of invasive disease, were used to assess functional immunogenicity against each of the vaccine antigens by hSBA:

- fHBP antigen: strain 44/76
- NadA antigen: strain 5/99
- immunodominant PorA P1.4 component of OMV: strain NZ98/254
- NHBA antigen: strain M10713

** pre-booster time point represents persistence of bactericidal antibody at 8 months after BEXSERO vaccination at 2, 3 and 4 months of age and 6 months after BEXSERO vaccination at 2, 4 and 6 months of age.

*** % seropositive = the percentage of participants who achieved an hSBA ≥ 1:5.

**** GMT = geometric mean titre.

Two-dose primary schedule followed by a booster

The immunogenicity after two doses (at 3 and a half and 5 months of age) or three doses (at 2 and a half, 3 and a half and 5 months of age) of BEXSERO, followed by a booster, has been evaluated in an additional phase 3 clinical study (V72_28). The percentages of seropositive subjects (i.e. achieving an hSBA of at least 1:4 to the fHPB, NadA, PorA P1.4 and/or NHBA antigens) ranged from 44% to 100% one month after the second dose and from 55% to 100% one month after the third dose. At one month following a booster administered 6 months after the last dose, the percentages of seropositive to the fHPB, NadA, PorA P1.4 and/or NHBA antigens ranged from 87% to 100% for the two-dose schedule, and from 83% to 100% for the three-dose schedule.

Antibody persistence was evaluated in an extension study in children 3 to 4 years of age (V72_28E1). Comparable percentages of subjects were seropositive at 2 to 3 years after being previously vaccinated in infancy with either two doses followed by a booster of BEXSERO at 11 months (ranging from 35% to 91%) or three doses in infancy followed by a booster at 11 months (ranging from 36% to 84%). In the same study the response to an additional dose administered 2 to 3 years after the 11-month booster was indicative of immunological memory as shown by a robust antibody response against all 4 BEXSERO antigens, ranging from 81% to 100% and from 70% to 99%, respectively. These observations are consistent with adequate priming in infancy with both a two-dose and a three-dose primary series followed by a booster of BEXSERO.

Immunogenicity in infants 6 to 11 months of age and children 12 to 23 months of age

Bactericidal responses following two doses administered two months apart to children 6 months to 23 months of age were investigated in two studies (V72P9 and V72P13E1). Baseline GMTs were uniformly low against all reference strains in each study, ranging from 1.00 to 2.32. After the two-dose series seropositivity rates and hSBA GMTs were high against each of the vaccine antigens and were similar for infants vaccinated at 6 and 8 months of age and toddlers vaccinated at 13 and 15 months of age. (See Table 4). Data on antibody persistence one year after the two doses at 13 and 15 months of age are also summarised in Table 4 (V72P13E2).

Table 4: Serum bactericidal antibody responses following BEXSERO vaccination at 6 and 8 months of age (Study V72P9), or 13 and 15 months of age (Study V72P13E1) and persistence of bactericidal antibody one year after the two doses at 13 and 15 months of age (Study V72P13E2)

Antigen*	Response (95% CI)	Age of vaccination	
		6, 8 months	13, 15 months
fHBP	1 month after 2nd dose	N = 23	N = 163
	% seropositive**	100% (85 – 100)	100% (98 – 100)
	hSBA GMT***	250 (173 – 361)	271 (237 – 310)
	12 months after 2nd dose	-	N = 68
	% seropositive		74% (61 – 83)
	hSBA GMT		14 (9.4 – 20)
NadA	1 month after 2nd dose	N = 23	N = 164
	% seropositive**	100% (85 – 100)	100% (98 – 100)
	hSBA GMT***	534 (395 – 721)	599 (520 – 690)
	12 months after 2nd dose	-	N = 68
	% seropositive		97% (90 – 100)
	hSBA GMT		70 (47 – 104)
PorA P1.4	1 month after 2nd dose	N = 22	N = 164
	% seropositive**	95% (77 – 100)	100% (98 – 100)
	hSBA GMT***	27 (21 – 36)	43 (38 – 49)
	12 months after 2nd dose	-	N = 68
	% seropositive		18% (9 – 29)
	hSBA GMT		1.65 (1.2 – 2.28)
NHBA	1 month after 2nd dose	-	N = 46
	% seropositive**		63% (48 – 77)
	hSBA GMT***		11 (7.07 – 16)
	12 months after 2nd dose	-	N = 65
	% seropositive		38% (27 – 51)
	hSBA GMT		3.7 (2.15 – 6.35)

* The following strains of group B meningococci, which were isolated from cases of invasive disease, were used to assess functional immunogenicity against each of the vaccine antigens by hSBA:

- fHBP antigen: strain 44/76
- NadA antigen: strain 5/99
- immunodominant PorA P1.4 component of OMV: strain NZ98/254
- NHBA antigen: strain M10713

** % seropositive = the percentage of participants who achieved an hSBA ≥ 1:4 (in the 6 to 11 months of age) in study V72P9 and an hSBA ≥ 1:5 (in the 12 to 23 months range of age) in studies V72P13E1 and V72P13E2.

***GMT = geometric mean titre.

The seroresponse rates were 98% to 100% against all strains following a booster dose given at approximately one year after the administration of two doses at 13 and 15 months of age.

An increase in hSBA titres for the four reference strains was recorded in an additional group of 43-68 children evaluated after vaccination with BEXSERO at 12 and 14 months of age in study V72P13E1. Post-vaccination seropositivity rates were: 100% for strain 44/76 and strain 5/99; 96% for strain NZ98/254; and 74% for strain M10713.

Immunogenicity in children 2 to 10 years of age
The immunogenicity after two doses of BEXSERO administered either one or two months apart in children 2 to 10 years of age has been evaluated in an initial phase 3 clinical study and its extension (V72_28 and V72_28E1). In the initial study (V72_28), whose results are summarised in Table 5, participants received two doses of BEXSERO two months apart. The seroresponse rates and hSBA GMTs were high after the two-dose schedule in children against each of the vaccine antigens (Table 5).

Table 5: Serum bactericidal antibody responses at 1 month following the second dose of BEXSERO given to children 2 to10 years of age following a 0-, 2-month schedule

Antigen		2 to 5 years of age	6 to 10 years of age
fHbp	% seropositive* (95% CI)	N=99 100% (96-100)	N=287 99% (96-100)
	hSBA GMT** (95% CI)	140 (112-175)	112 (96-130)
NadA	% seropositive (95% CI)	N=99 99% (95-100)	N=291 100% (98-100)
	hSBA GMT (95% CI)	584 (466-733)	457 (392-531)
PorA P1.4	% seropositive (95% CI)	N=100 98% (93-100)	N=289 99% (98-100)
	hSBA GMT (95% CI)	42 (33-55)	40 (34-48)
NHBA	% seropositive (95% CI)	N=95 91% (83-96)	N=275 95% (92-97)
	hSBA GMT (95% CI)	23 (18-30)	35 (29-41)

* % seropositive = the percentage of subjects who achieved an hSBA ≥ 1:4 (against reference strains for fHbp, NadA, PorA P1.4 antigens) and an hSBA ≥ 1:5 (against reference strain for NHBA antigen).
** GMT = geometric mean titre.

In the extension study (V72_28E1), in which two doses of BEXSERO were administered one month apart in unvaccinated children, high percentages of subjects aged 3-10 years were seropositive after the second dose. An early immune response after the first dose was also evaluated. The percentages of seropositive subjects (i.e. achieving an hSBA of at least 1:4) against fHPB, NadA, PorA P1.4 and/or NHBA antigens ranged from 46% to 95% at one month after the first dose and from 69% to 100% at one month after the second dose.

This study also evaluated antibody persistence and the response to a booster dose in children who received the two-dose primary series at 2 to 5 or 6 to 10 years of age. After 24 to 36 months, the percentages of seropositive subjects (i.e. achieving an hSBA of at least 1:4) declined, ranging across strains from 21% to 74% in children 4 to 7 years of age and from

47% to 86% in children 8 to 12 years of age. The response to a booster dose administered 24 to 36 months after the primary series was indicative of immunological memory as the percentages of seropositive subjects ranged across strains from 93% to 100% in children 4 to 7 years of age and from 96% to 100% in children 8 to 12 years of age.

Immunogenicity in adolescents (from 11 years of age) and adults
Participants aged 11 to 17 years (study V72P10) received two doses of BEXSERO with a 1-, 2- or 6-month interval between doses. Baseline GMTs ranged from 2.64 to 4.11. As early as one month after the first dose, percentages of participants who achieved an hSBA ≥ 1:4 ranged from 90% to 97%. Antibody persistence was demonstrated 18 to 23 months after the second dose. (see Table 6). Independent of pre-vaccination seropositivity status, a high percentage of participants were seropositive and achieved 4-fold increases in hSBA titres post vaccination (see Table 7).

Table 6: Serum bactericidal antibody responses in adolescents one month after one and two doses of BEXSERO administered according to different two-dose schedules and persistence of bactericidal antibody 18 to 23 months after the second dose

* The following strains of group B meningococci, which were isolated from cases of invasive disease, were used to assess functional immunogenicity against each of the vaccine antigens by hSBA:

- fHBP antigen: strain 44/76
- NadA antigen: strain 5/99
- immunodominant PorA P1.4 component of OMV: strain NZ98/254

** % seropositive = the percentage of participants who achieved an hSBA ≥ 1:4

Antibody persistence data for the study in adolescents were obtained in an extension phase 3 study. At approximately 7.5 years after the two-dose primary series, the percentages of subjects with hSBA ≥ 1:4 declined, ranging across strains from 29% to 84%. The response to a booster dose administered 7.5 years after the primary series was indicative of immunological memory as the percentages of subjects reaching an hSBA ≥ 1:4 across strains ranged from 93% to 100%.

The same study also evaluated antibody persistence data from an additional phase 3 initial study in adolescents. At approximately 4 years after the two-dose primary series, the percentages of subjects with hSBA ≥ 1:5 generally declined from a range across strains of 68% to 100% after the second dose to a range across strains of 9% to 84%. The response to a booster dose administered 4 years after the primary series was indicative of immunological memory as the percentages of subjects with hSBA ≥ 1:5 ranged across strains from 92% to 100%.

In studies of adults aged 18 to 50 years (V72P4) and 18 to 40 years (V72P5), data were obtained after the two doses of BEXSERO with a 1 month or 2 month interval between doses. (see Table 8). Baseline GMTs against reference strains ranged from 1.71 to 4.06. Responses in adults were similar to those of adolescents.

Table 8: Serum bactericidal antibody responses in adults after two doses of BEXSERO administered according to different two-dose schedules

Antigen*	**Response (95% CI)**	**0, 1 months**	**0, 2 months**
fHBP	1 month after 2nd dose	N=28	N=46
	% seropositive**	100% (88-100)	100% (92-100)

PorA P1.4	1 month after 2nd dose	N=28	N=46
	% seropositive	96% (82-100)	91% (79-98)
	hSBA GMT	47 (30-75)	32 (21-48)

*The following strains of group B meningococci, which were isolated from cases of invasive disease, were used to assess functional immunogenicity against each of the vaccine antigens by hSBA:

- fHBP antigen: strain 44/76
- NadA antigen: strain 5/99
- immunodominant PorA P1.4 component of OMV: strain NZ98/254

** % seropositive = the percentage of participants who achieved an hSBA ≥ 1:4.

*** GMT = geometric mean titre.

Serum bactericidal response to NHBA antigen has not been evaluated.

Immunogenicity in special populations

Children and adolescents with complement deficiencies, asplenia, or splenic dysfunction.

In a phase 3 clinical study, children and adolescents 2 to 17 years of age with complement deficiencies (40), with asplenia or splenic dysfunction (107), and age-matched healthy participants (85) received two doses of BEXSERO two months apart. At 1 month following the 2-dose vaccination course, the percentages of participants with hSBA ≥ 1:5 in individuals with complement deficiencies and asplenia or splenic dysfunction were 87% and 97% for antigen fHbp, 95% and 100% for antigen NadA, 68% and 86% for antigen PorA P1.4, 73% and 94% for antigen NHBA, respectively, indicating an immune response in these immunocompromised participants. The percentages of healthy participants with hSBA ≥ 1:5 were 98% for antigen fHbp, 99% for antigen NadA, 83% for antigen PorA P1.4, and 99% for antigen NHBA.

5.2 PHARMACOKINETIC PROPERTIES

Not applicable for vaccines.

5.3 PRECLINICAL SAFETY DATA

Genotoxicity

Genotoxicity studies have not been performed with BEXSERO.

Carcinogenicity

Carcinogenicity studies have not been performed with BEXSERO.

6 PHARMACEUTICAL PARTICULARS

6.1 LIST OF EXCIPIENTS

BEXSERO contains the excipients sodium chloride, histidine, sucrose and water for injections.

6.2 INCOMPATIBILITIES

Incompatibilities were either not assessed or not identified as part of the registration of this medicine.

6.3 SHELF LIFE

In Australia, information on the shelf life can be found on the public summary of the Australian Register of Therapeutic Goods (ARTG). The expiry date can be found on the packaging.

6.4 SPECIAL PRECAUTIONS FOR STORAGE

Store in a refrigerator (2°C to 8°C). Do not freeze. Protect from light.

6.5 NATURE AND CONTENTS OF CONTAINER

BEXSERO is presented as a 0.5 mL suspension in a pre-filled syringe (type I glass) with a plunger stopper (butyl rubber) and with a rubber tip cap.

The tip cap and rubber plunger stopper of the pre-filled syringe are not made with natural rubber latex.

BEXSERO is supplied in packs of 1 syringe with or without a needle or packs of 10 syringes without needles.

Not all pack sizes may be distributed in Australia.

6.6 SPECIAL PRECAUTIONS FOR DISPOSAL

In Australia, any unused medicine or waste material should be disposed of in accordance with local requirements.

6.7 PHYSICOCHEMICAL PROPERTIES

Not applicable for vaccines.

7 MEDICINE SCHEDULE (POISONS STANDARD)

Schedule 4 – Prescription Only Medicine

8 SPONSOR

GlaxoSmithKline Australia Pty Ltd
Level 4, 436 Johnston Street,
Abbotsford, Victoria, 3067

9 DATE OF FIRST APPROVAL

14 Aug 2013

10 DATE OF REVISION

19 May 2026

SUMMARY TABLE OF CHANGES

Section Changed	Summary of new information
4.8	Inclusion of data relating to the breadth of the immune response
5.1	Inclusion of real world data

Version 15.0
