AUSTRALIAN PRODUCT INFORMATION – REXULTI® (BREXPIPRAZOLE) FILM-COATED TABLETS

1 NAME OF THE MEDICINE

Brexpiprazole.

2 QUALITATIVE AND QUANTITATIVE COMPOSITION

REXULTI contains brexpiprazole, a novel atypical antipsychotic agent. REXULTI is available as 0.25 mg, 0.5 mg, 1 mg, 2 mg, 3 mg and 4 mg tablets for oral use.

Excipient with known effect: lactose.

For the full list of excipients, see Section 6.1 List of excipients.

3 PHARMACEUTICAL FORM

REXULTI (brexpiprazole) tablets are available as:

Strength	Shape	Colour	Marking
0.25 mg*	Round, shallow convex and bevel-edged	light brown	debossed with BRX and 0.25 on one side
0.5 mg	Round, shallow convex and bevel-edged	light orange	debossed with BRX and 0.5 on one side
1 mg	Round, shallow convex and bevel-edged	light yellow	debossed with BRX and 1 on one side
2 mg	Round, shallow convex and bevel-edged	light green	debossed with BRX and 2 on one side
3 mg	Round, shallow convex and bevel-edged	light purple	debossed with BRX and 3 on one side
4 mg	Round, shallow convex and bevel-edged	white	debossed with BRX and 4 on one side

^{*} Not currently marketed

4 CLINICAL PARTICULARS

4.1 Therapeutic indications

REXULTI is indicated in adult patients for the:

- Treatment of schizophrenia.
- Treatment of agitation associated with Alzheimer's dementia (AAD), in patients who are unresponsive to non-pharmacological interventions.

4.2 Dose and method of administration

Treatment of Schizophrenia

The recommended starting dose for REXULTI in the treatment of patients with schizophrenia is 1 mg once daily on Days 1 to 4.

The recommended target dose range is 2 mg to 4 mg once daily. Titrate to 2 mg once daily on Day 5, then to 4 mg on Day 8 based on the patient's clinical response and tolerability. The maximum recommended daily dosage is 4 mg.

Maintenance treatment: The recommended maintenance dose range is 2 mg/day to 4 mg/day. Periodically reassess to determine the continued need for maintenance treatment and appropriate dosage.

Treatment of Agitation Associated with Alzheimer's Dementia

The recommended starting dosage for REXULTI for the treatment of AAD is 0.5 mg taken once daily on Days 1 to 7. The dosage should be titrated on Days 8 through 14 to 1 mg, and on Day 15 to 2 mg.

The recommended target dosage range is 2 mg to 3 mg once daily. After at least 28 days at 2 mg once daily, the dose can be increased to the maximum recommended daily dose of 3 mg, if clinically warranted. The maximum daily dose of 3 mg should not be exceeded for the treatment of AAD.

There are no placebo-controlled trial data to support treatment beyond 12 weeks in patients with agitation associated with Alzheimer's dementia (AAD), who are unresponsive to non-pharmacological interventions.

Prior to the initiation and under REXULTI treatment, patients with agitation in Alzheimer's dementia should be evaluated and appropriately treated, if applicable, for any reversible factors leading to agitation (e.g. pain, infection, polypharmacy, acute delirium) and should have been found unresponsive to nonpharmacological interventions.

Assess efficacy after 12 weeks of treatment and periodically thereafter to determine the continued need for maintenance treatment and appropriate dosage. Discontinue treatment in case of unsatisfactory treatment response. REXULTI should not be used as an "as needed" treatment of AAD. REXULTI can be given with or without food.

REXULTI has not been evaluated in patients with dysphagia, limited oral intake and/or enteral feeding tubes.

Switching from Other Antipsychotics

There are no systematically collected data to specifically address switching patients with schizophrenia or AAD from other antipsychotics to REXULTI or concerning concomitant administration with other antipsychotics. While immediate discontinuation of the previous antipsychotic treatment may be acceptable for some patients with schizophrenia, more gradual discontinuation may be most appropriate for others. In all cases, the period of overlapping antipsychotic administration should be minimized.

Missed Dose

If a dose is missed, then it should be taken as soon as possible unless it is close to the next dose. Two doses should not be taken.

Use in Elderly

The safety and efficacy of REXULTI in patients with schizophrenia 65 years of age or older, or in patients with AAD 90 years of age or older, have not been established. Caution should be used when treating elderly patients (see Section 4.4 Special warnings and precautions for use).

Similar exposure to brexpiprazole was seen when REXULTI was administered in healthy elderly subjects (older than 65 years) and in adult subjects (18-45 years old). (See Section 5.2 Pharmacokinetic properties) In general, dose selection for an elderly patient should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, and cardiac function, concomitant diseases, and other drug therapy.

Dosing Adjustment for Hepatic Impairment

For patients with moderate to severe hepatic impairment (Child-Pugh score ≥7), the maximum recommended dosage is 3 mg once daily for patients with schizophrenia and 2 mg once daily for patients with AAD.

Dosing Adjustment for Renal Impairment

For patients with moderate, severe or end-stage renal impairment (creatinine clearance CL_{cr} <60 mL/minute), the maximum recommended dosage is 3 mg once daily for patients with schizophrenia and 2 mg once daily for patients with AAD.

Other Special Populations

No dosage adjustment for REXULTI is required on the basis of a patient's sex, race, or smoking status. (See Section 5.2 Pharmacokinetic properties)

Dosing Modifications for CYP2D6 Poor Metabolisers and for Concomitant Use with CYP Inhibitors/Inducers

Factors	Adjusted dose			
CYP2D6 Poor Metabolisers				
Known CYP2D6 poor metabolisers	Administer half of the usual dose			
Known CYP2D6 poor metabolisers taking	Administer a quarter of the usual dose			
strong/moderate CYP3A4 inhibitors				
Patients Taking CYP2D6 Inhibitors and/or CYP3A4 Inhibitors				
Strong CYP2D6 inhibitors	Administer half of the usual dose			
Strong CYP3A4 inhibitors				
Strong/moderate CYP2D6 inhibitors with	Administer a quarter of the usual dose			
strong/moderate CYP3A4 inhibitors				
Patients Taking CYP3A4 Inducers				
Strong CYP3A4 inducers*	Double usual dose over 1 to 2 weeks			

^{*} If the co-administered CYP3A4 inducer is discontinued, reduce the dosage to the original level over 1 to 2 weeks.

Abuse potential

Brexpiprazole showed neither a potential to produce physical dependence in rats nor a reinforcing effect in rhesus monkeys. In a drug abuse liability study in rats, no withdrawal

signs suggestive of physical dependence were evident. Brexpiprazole is not considered to have potential to produce physical dependence.

4.3 Contraindications

Hypersensitivity to the active substance or to any of the excipients.

4.4 Special warnings and precautions for use

Increased Mortality in Elderly Patients with Dementia-related Psychosis

Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death compared to placebo.

Analyses of 17 placebo-controlled trials (modal duration of 10 weeks), largely in patients taking atypical antipsychotic drugs, revealed a risk of death in the drug-treated patients of between 1.6 to 1.7 that in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in the drug-treated patients was about 4.5%, compared to a rate of about 2.6% in placebo-treated patients. In patients with Alzheimer's dementia, REXULTI is only approved for the treatment of agitation and is not approved for the treatment of dementia-related psychosis or agitation due to other conditions (e.g. acute delirium).

CNS disorders other than Alzheimer's Dementia (AD)

AAD patients with acute delirium, or delirium within 30 days, dementia or other memory impairment not due to Alzheimer's disease were excluded from the REXULTI clinical development program. REXULTI should not be used for the treatment of acute confusional states and should not be used to treat agitation in patients with dementia related to medical conditions other than AD.

Cerebrovascular Adverse Reactions

In placebo-controlled trials with some antipsychotic drugs in elderly patients with dementia, there was a higher incidence of cerebrovascular adverse reactions (cerebrovascular accidents and transient ischaemic attacks), including fatalities, compared to placebo.

QT prolongation

AAD patients with preexisting QTcF \geq 450 msec in men and \geq 470 msec in women have not been studied in the REXULTI AAD clinical development program. Any co-medication with the potential to induce QT prolongation was not studied in the AAD clinical development program.

Cardiovascular disorders

AAD patients with clinically significant pre-existing cardiovascular disorders (including uncontrolled atrial fibrillation, heart failure, or ischaemic heart disease) have not been studied in the REXULTI clinical development program.

Suicidal Risk

The possibility of a suicide attempt is inherent in psychotic illnesses. Close supervision and appropriate clinical management of high-risk patients should accompany drug therapy.

Venous thromboembolism

Cases of venous thromboembolism (VTE) have been reported with antipsychotic drugs. Since patients treated with antipsychotics often present with acquired risk factors for VTE, all possible risk factors for VTE should be identified before and during treatment with REXULTI and preventive measures undertaken. AAD patients with a history of VTE have not been studied in the REXULTI clinical development program

Neuroleptic Malignant Syndrome (NMS)

A potentially fatal symptom complex sometimes referred to as Neuroleptic Malignant Syndrome (NMS) has been reported in association with administration of antipsychotic drugs including REXULTI. Clinical manifestations of NMS are hyperpyrexia, muscle rigidity, altered mental status and evidence of autonomic instability (irregular pulse or blood pressure, tachycardia, diaphoresis and cardiac dysrhythmia). Additional signs may include elevated creatine phosphokinase, myoglobinuria (rhabdomyolysis), and acute renal failure. If a patient develops signs and symptoms indicative of NMS or presents with unexplained high fever without additional clinical manifestations of NMS, all antipsychotic drugs including REXULTI must be discontinued. If a patient requires antipsychotic drug treatment after recovery from NMS, the potential reintroduction of drug therapy should be carefully considered.

Tardive Dyskinesia

A syndrome of potentially irreversible, involuntary, dyskinetic movements may develop in patients treated with antipsychotic drugs. Although the prevalence of the syndrome appears to be highest among the elderly, especially elderly women, it is impossible to rely upon prevalence estimates to predict, at the inception of antipsychotic treatment, which patients are likely to develop the syndrome.

If signs and symptoms of tardive dyskinesia appear in a patient treated with REXULTI, dose reduction or discontinuation should be considered. These symptoms can temporally deteriorate or can even arise after discontinuation of treatment.

Metabolic Parameters

Hyperglycaemia and Diabetes Mellitus

Hyperglycaemia and diabetes mellitus, in some cases extreme and associated with ketoacidosis or hyperosmolar coma or death, have been reported in patients treated with atypical antipsychotics.

Patients treated with any antipsychotic agents should be observed for signs and symptoms of hyperglycaemia (such as polydipsia, polyuria, polyphagia and weakness) and patients with diabetes mellitus or with risk factors for diabetes mellitus (e.g., obesity, family history of diabetes) should be monitored regularly for worsening of glucose control. In patients with significant treatment-emergent hyperglycaemia, discontinuation of REXULTI should be considered.

Schizophrenia

In clinical trials with REXULTI in patients with schizophrenia (Trials 1 and 2) changes in fasting glucose were comparable between REXULTI- and placebo-treated subjects.

In the long-term maintenance trial (Trial 3), the mean changes from baseline to last visit in serum glucose were also small for the REXULTI (0.11 mmol/L) and placebo (-0.09 mmol/L) groups, and not considered clinically relevant.

In the long-term, open-label studies, the mean change from baseline to last visit in fasting serum glucose was 0.12 mmol/L (N=1120).

Agitation Associated with Alzheimer's Dementia

In the 12-week placebo-controlled, fixed-dose studies in patients (51 to 90 years of age) with AAD, the proportions of patients with shifts in fasting glucose from normal (<5.6 mmol/L) to high (≥7.0 mmol/L) or impaired (≥5.6 and <7.0 mmol/L) to high were similar in patients treated with REXULTI (14%) and patients treated with placebo (16%).

Of the patients (55 to 90 years of age) from the 12-week placebo-controlled, fixed-dose clinical study, who rolled over into a 12-week, active-treatment extension study, 14% of patients with normal baseline fasting glucose experienced a shift from normal (<5.6 mmol/L) to high (≥7.0 mmol/L) while taking REXULTI; 24% of patients with impaired fasting glucose experienced shifts from impaired (≥5.6 and <7.0 mmol/L) to high. Combined, 18% of patients with normal or impaired fasting glucose experienced shifts to high fasting glucose. AAD patients with unstable or uncontrolled diabetes mellitus have not been studied in the REXULTI clinical development program.

Weight Gain and Dyslipidaemia

Antipsychotic drugs have been associated with metabolic changes, including weight gain and dyslipidaemia. Clinical monitoring of body weight is recommended. (See Section 4.8 Adverse Effects – Weight Gain and Section 4.8 Adverse Effects – Dyslipidaemia).

Orthostatic Hypotension and Syncope

In the short-term, placebo-controlled clinical studies of REXULTI in subjects with schizophrenia, the incidence of orthostatic hypotension-related adverse reactions in REXULTI-treated subjects compared to placebo-treated subjects included: dizziness (2.3% versus 1.4%), orthostatic hypotension (0.4% versus 0.2%), and syncope (0.1% versus 0%).

In 12-week, placebo-controlled clinical studies of REXULTI in patients with AAD, the incidence of orthostatic hypotension-related adverse reactions in patients treated with REXULTI compared to patients treated with placebo included: dizziness (3% versus 3%), orthostatic hypotension (1% versus 1%), and syncope (0.2% versus 0.8%). AAD patients with a history of orthostatic hypotension were excluded from the REXULTI clinical development program.

Adverse reactions related to orthostatic hypotension can include dizziness, light-headedness and tachycardia. Generally, these risks are greatest at the beginning of treatment and during

dose escalation. Patients at increased risk of these adverse reactions or at increased risk of developing complications from hypotension include those with dehydration, hypovolemia, treatment with antihypertensive medication, history of cardiovascular disease (e.g., heart failure, myocardial infarction, ischaemia, or conduction abnormalities), history of cerebrovascular disease, as well as patients who are antipsychotic-naïve. In such patients, consider using a lower starting dose and slower titration, and monitor orthostatic vital signs.

QT interval

In a thorough QTc study in patients with schizophrenia or schizoaffective disorder, REXULTI did not prolong QT interval (see also Section 5.1 Pharmacodynamic properties). However, in patients with a family history of QT prolongation antipsychotics should be used with caution.

Seizures

As with other antipsychotic drugs, REXULTI should be used cautiously in patients with a history of seizures or with conditions that potentially lower the seizure threshold. AAD patients with a history of epilepsy and/or using antiepileptic medication have not been studied in the REXULTI clinical development program.

Body Temperature Regulation

Disruption of the body's ability to reduce core body temperature has been attributed to antipsychotic agents. Appropriate care is advised when prescribing REXULTI for patients who will be experiencing conditions that may contribute to an elevation in core body temperature, e.g., exercising strenuously, exposure to extreme heat, receiving concomitant medication with anticholinergic activity, or being subject to dehydration.

Dysphagia

Oesophageal dysmotility and aspiration have been associated with antipsychotic drug use. REXULTI and other antipsychotic drugs should be used cautiously in patients at risk of aspiration pneumonia.

Leukopenia, Neutropenia and Agranulocytosis

Leukopenia/neutropenia has been reported during treatment with antipsychotic agents. Agranulocytosis (including fatal cases) has been reported with other agents in the class.

Possible risk factors for leukopenia/neutropenia include pre-existing low white blood cell count (WBC) and history of drug-induced leukopenia/neutropenia. Patients with a pre-existing low WBC or a history of drug-induced leukopenia/neutropenia should have their complete blood count (CBC) monitored frequently during the first few months of therapy and REXULTI should be discontinued at the first sign of decline in WBC, in the absence of other causative factors.

Patients with neutropenia should be carefully monitored for fever or other symptoms or signs of infection and treated promptly if such symptoms or signs occur. Patients with severe neutropenia (absolute neutrophil count < 1000/mm³) should discontinue REXULTI and have their WBC followed until recovery.

Impulse Control Disorders

Post-marketing reports of impulse-control disorders including gambling have been reported very rarely with antipsychotics, including brexpiprazole. Patients with a prior history of impulse-control disorders may be at increased risk and should be monitored carefully. It should be noted that impulse-control symptoms can be associated with the underlying disorder.

Sleep apnoea

Sleep apnoea and related disorders have been reported in patients treated with antipsychotic medications, with or without prior history of sleep apnoea, and with or without concomitant weight-gain. In patients who have a history of or are at risk for sleep apnoea, or who are concomitantly using central nervous system depressants, REXULTI should be used with caution.

Lactose

REXULTI tablets contain lactose. Patients with rare hereditary problems of galactose intolerance, the Lapp lactase deficiency, or glucose-galactose malabsorption should not take this medicine.

Use in hepatic impairment

In patients with hepatic impairment, dosage adjustment is required. (See Section 5.2 Pharmacokinetic properties and Section 4.2 Dose and method of administration)

Use in renal impairment

In patients with renal impairment, dosage adjustment is required. (See Section 5.2 Pharmacokinetic properties and Section 4.2 Dose and method of administration)

Use in the elderly

Clinical studies of REXULTI included limited numbers of subjects aged 65 and older with schizophrenia and 90 years of age and older with AAD, to allow for determining whether they respond differently than younger subjects. Elderly subjects (older than 65 years old) exhibited similar brexpiprazole systemic exposure in comparison with adult subjects (18-45 years old) (See Section 5.2 Pharmacokinetic properties and Section 4.2 Dose and method of administration). Elderly patients with dementia-related psychosis treated with antipsychotic drugs are at an increased risk of death compared to placebo (see Section 4.4 Special warnings and precautions for use – Increased Mortality in Elderly Patients with Dementia-related Psychosis).

Paediatric use

Safety and effectiveness in patients under the age of 18 years has not yet been evaluated.

Effects on laboratory tests

No data available.

4.5 Interactions with other medicines and other forms of interactions

REXULTI is predominantly metabolised by CYP3A4 and CYP2D6. Based on results of drug interaction trials, dose adjustment to half the maintenance dose is recommended for subjects administered strong CYP2D6 or CYP3A4 inhibitors. Based on estimations from the population pharmacokinetic analysis, CYP2D6 extensive metabolisers (EM) receiving both CYP3A4 and CYP2D6 inhibitors or CYP2D6 poor metabolisers (PM) receiving strong CYP3A4 inhibitors are expected to have an approximately 4-5 fold increase in brexpiprazole concentrations; therefore, the REXULTI dose should be reduced to ¼ of the recommended dosage in these situations (see Section 4.2 Dose and method of administration).

If REXULTI is used concomitantly with a strong CYP3A4 inducer (i.e., rifampicin), it is necessary to increase the dose by two fold and further adjust it based on clinical response (see Section 4.2 Dose and method of administration).

Quinidine and Other Strong CYP2D6 Inhibitors

Co-administration of a 2 mg single oral dose of REXULTI with quinidine (324 mg/day for 7 days), a potent inhibitor of CYP2D6, increased the AUC of brexpiprazole by 94%.

Ketoconazole and Other Strong CYP3A4 Inhibitors

Co-administration of ketoconazole (200 mg twice daily for 7 days), a potent inhibitor of CYP3A4, with a 2 mg single oral dose of REXULTI increased the AUC of brexpiprazole by 97%.

Ticlopidine and Other CYP2B6 Inhibitors

Co-administration of a 2 mg single oral dose of REXULTI with ticlopidine (250 mg twice daily for 7 days), a potent inhibitor of CYP2B6, had no effect on the pharmacokinetics of brexpiprazole.

Rifampicin and Other CYP3A4 Inducers

Co-administration of rifampin (600 mg twice daily for 12 days), a potent CYP3A4 inducer, with a single 4 mg oral dose of REXULTI resulted in an approximate 31% and 73% decrease in brexpiprazole C_{max} and AUC.

Gastric Acid pH Modifiers

Co-administration of omeprazole (40 mg once daily, 5 days), a widely used proton pump inhibitor (PPI), with a single oral dose of REXULTI (4 mg) resulted in no effect on absorption of brexpiprazole. Other gastric acid pH modifiers (PPIs, H2 receptor antagonists, etc.) are also not expected to affect the absorption of brexpiprazole.

Potential for REXULTI to Affect Other Drugs

Based on results of *in vitro* studies, brexpiprazole is unlikely to cause clinically important pharmacokinetic interactions with drugs metabolised by cytochrome P450 enzymes. Clinical studies show that oral REXULTI (2 mg/day, 11 days) had no effect on the metabolism of dextromethorphan (a CYP2D6 substrate), lovastatin (a CYP3A4 substrate) or bupropion (a CYP2B6 substrate). REXULTI does not affect absorption of drugs that are substrates of the BCRP transporter (rosuvastatin) or the P-gp transporter (fexofenadine).

As with other antipsychotics, caution should be used if brexpiprazole is administered concomitantly with medicinal products known to cause QT prolongation or electrolyte imbalance.

4.6 Fertility, pregnancy and lactation

Effects on fertility

Drugs with D_2 -antagonist properties are potential causes of hypothalamic-pituitary-gonadal axis disruption. Brexpiprazole was given once daily by oral gavage to female rats at doses of 0, 0.3, 3 or 30 mg/kg/day prior to mating with untreated males and continuing through conception and implantation. Prolonged diestrus and decreased fertility were observed at 3 and 30 mg/kg/day, with exposure (plasma AUC) \geq 0.2 fold the clinical exposure at the 4 mg MRHD. At 30 mg/kg/day (AUC exposure 4-fold clinical exposure) a doubling of the mating phase and significantly increased preimplantation losses were seen. The no observed adverse effect level for brexpiprazole was 0.3 mg/kg/day (AUC exposure <0.2-fold clinical exposure).

Brexpiprazole was given once daily by oral gavage to male rats at doses of 0, 3, 10 or 100 mg/kg/day, with exposure (plasma AUC) up to 18-fold the clinical exposure at the 4 mg MRHD. Following 63 days of dosing (one spermatic cycle), treated males were cohabited with untreated females for a maximum of 14 days. No noticeable differences were noted in the duration of mating or fertility indices in any brexpiprazole treated group. Testicular lesions including atrophy of the seminiferous tubule were observed at doses of 30 mg/kg/day and higher (AUC exposure \geq 6-fold clinical exposure) in repeat-dose toxicity studies, and a decrease in sperm in the epididymis was observed at 300 mg/kg/day (AUC exposure 37-fold clinical exposure) with minimal incidence (2 of 15 rats).

Use in Pregnancy (Category C)

Safe use of REXULTI during pregnancy or lactation has not been established. Therefore, use of REXULTI in pregnancy, in nursing mothers, or in women of childbearing potential requires that the benefits of treatment be weighed against the possible risks to mother and child.

Neonates exposed to antipsychotic drugs during the third trimester of pregnancy are at risk of extrapyramidal and/or withdrawal symptoms following delivery. There have been reports of agitation, hypertonia, hypotonia, tremor, somnolence, respiratory distress and feeding disorder in these neonates. These complications have varied in severity; while in some cases symptoms have been self-limited, in other cases neonates have required intensive care unit support and prolonged hospitalisation.

The effect of REXULTI on labour and delivery in humans is unknown. Parturition in rats was not affected by brexpiprazole.

Animal data

Brexpiprazole was not teratogenic and did not cause adverse developmental effects in embryofoetal developmental toxicity studies in which pregnant rats and rabbits were given

brexpiprazole during the period of organogenesis at oral doses up to 30 mg/kg/day (with respective exposures (plasma AUC) 4-fold and 7-fold the clinical exposure at the 4 mg/day MRHD).

In the rabbit study an oral dose that induced severe maternal toxicity (150 mg/kg/day, AUC exposure 21-fold clinical exposure) was associated with decreased body weight, retarded ossification, and increased incidences of visceral and skeletal variations in foetuses.

When pregnant rats were administered brexpiprazole orally during the period of organogenesis through lactation, the number of perinatal deaths of pups was increased at 30 mg/kg/day (plasma AUC exposure 4-fold exposure at the 4 mg/day MRHD); the no-effect dose was 10 mg/kg/day (exposure similar to clinical exposure).

Use in lactation

Brexpiprazole and/or its metabolites was excreted in milk of rats during lactation, with milk levels about 1-2-fold maternal blood levels. It is not known whether brexpiprazole or its metabolites are excreted in human milk. Because of the potential for serious, potentially long-lived, adverse reactions in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug considering the risk of drug discontinuation to the mother.

4.7 Effects on ability to drive and use machines

As with other antipsychotics that have the potential to impair judgment, thinking or motor skills, patients should be cautioned about operating hazardous machinery including motor vehicles until they are certain that REXULTI therapy does not affect them adversely.

In the short-term, placebo-controlled clinical trials in patients with schizophrenia, somnolence (including sedation and hypersomnia) was reported in 5% of REXULTI-treated patients compared to 4% of placebo-treated patients.

In the 12-week, placebo-controlled, clinical studies in patients with AAD (aged 51 to 90 years), somnolence (including sedation) was reported in 24 (3.7%) of REXULTI-treated patients compared to 7 (1.8%) of placebo-treated patients.

4.8 Adverse effects (Undesirable effects)

Schizophrenia

The following findings are based on the two 6-week, placebo-controlled, fixed-dose clinical trials (Trials 1 and 2) in schizophrenia in which REXULTI was administered at daily doses of 1 mg, 2 mg and 4 mg (n=852), and the long-term maintenance trial (Trial 3) with REXULTI 1-4mg/day (n=97)

Common Adverse Reactions: There are no common adverse reactions that meet the criteria "incidence ≥5% and at least twice the rate of placebo" in Trials 1 and 2, the 6-week, placebo-controlled, fixed-dose trials, or Trial 3, the long-term maintenance trial.

Adverse reactions associated with REXULTI (incidence of 2% or greater and REXULTI incidence greater than placebo incidence) that occurred during acute therapy (up to 6 weeks in subjects with schizophrenia) and long-term therapy (up to 52 weeks) are shown in Table 1 and Table 2, respectively.

Table 1: Adverse Reactions Reported in ≥2% of REXULTI-treated Patients and that Occurred at Greater Incidence than Placebo-treated Patients in Fixed-dose Schizophrenia Trials (Trials1 and 2)^a

	RE	XULTI (brexp	iprazole, mg/d	ay)	
System Organ Class MedDRA Preferred Term	1 mg (N=120)	2 mg (N=368)	4 mg (N=364)	ALL (N=852)	Placebo (N=368)

Musculoskeletal Pain	2.1	1.0
Nervous System Disorders		
Tremor	3.1	0.0
Skin And Subcutaneous Tissue Disorders		
Pruritus	2.1	0.0

Discontinuations due to TEAEs occurred at less than half the rate in the REXULTI group (5.2%) compared with the placebo group (11.5%) in the double-blind maintenance phase of Trial 3. No subjects discontinued due to weight gain or akathisia.

Less Common Clinical Trial Adverse Drug Reactions (<2%)

Other adverse reactions (<2% frequency and greater than for placebo) in the short-term, fixed- dose placebo-controlled trials and the long-term maintenance trial in subjects with schizophrenia are shown below. The following listing does not include adverse reactions: 1) already listed in previous tables or elsewhere in the labelling, 2) for which a drug cause was remote, 3) which were so general as to be uninformative, or 4) which were not considered to have clinically significant implications.

Cardiovascular Disorders: Sinus Bradycardia, Atrioventricular Block First Degree, Palpitations

Endocrine Disorders: Hyperprolactinaemia

Eye Disorders: Vision Blurred, Blepharospasm

Gastrointestinal Disorders: Dry Mouth, Abdominal Pain, Flatulence, Dental Caries,

Abdominal Distension, Gastroesophageal Reflux Disease

General Disorders & Administration Site Conditions: Fatigue, Asthenia

Infections and Infestations: Upper Respiratory Tract Infection

Investigations: Hepatic Enzyme Increased

Musculoskeletal and Connective Tissue Disorders: Myalgia, Musculoskeletal Pain, Musculoskeletal Stiffness

Nervous System Disorders: Dizziness, Dyskinesia, Parkinsonism, Psychomotor Activity

Psychiatric Disorders: Abnormal Dreams, Bruxism

Skin and Subcutaneous Tissue Disorders: Rash

Vascular Disorders: Hypertension, Flushing, Hypotension

Abnormal Hematologic and Clinical Chemistry Findings

No clinically relevant mean changes from baseline in serum chemistry, haematology, urinalysis, or other laboratory test (insulin, fasting insulin and prolactin) results were observed during the clinical trials with REXULTI.

Agitation Associated with Alzheimer's Dementia (AAD)

The safety of REXULTI was evaluated in 655 patients (51 to 90 years of age), with a probable diagnosis of AAD, who participated in three 12-week placebo-controlled, clinical studies in which REXULTI was administered at daily doses of ≤1mg (157 patients), 2 mg (213 patients), 3 mg (153 patients) or flexible doses between 0.5 and 2 mg (132 patients). Eligible patients, who completed Trial 331-14-213, were also able to participate in an additional 12-week, active-treatment extension trial (331-201-00182). There were no additional safety findings during the extension trial.

Long-term data

A 12-week active-treatment extension study (Study 331-201-00182) to evaluate the safety and tolerability of brexpiprazole in patients with Agitation associated with dementia of the Alzheimer's type showed that long-term use of brexpiprazole (daily dosing with 2 or 3 mg after completion of 12 weeks of daily dosing with either placebo or 2 mg or 3 mg brexpiprazole) was generally safe and well tolerated in subjects with AAD and was associated with continued improvement in measures of agitation in subjects with Alzheimer's type dementia: After 12 weeks of treatment, mean CMAI total scores were similar between prior dose groups, with mean (SD) change from baseline greater in 86 subjects in the prior placebo group (-12.5 [16.6]) than in the 140 subjects in the prior brexpiprazole group (-7.1 [12.3]).

Discontinuation of Treatment Due to Adverse Events

The three 12-week placebo-controlled, clinical studies, a total of 6.3% (41/655) of patients treated with REXULTI and 3.4% (13/388) of patients treated with placebo discontinued due to adverse reactions.

Summary of Adverse Events Reported in ≥2 Patients Treated with REXULTI for AAD Adverse events associated with REXULTI (reported in ≥2 patients and greater than placebo) during the three 12-week clinical studies in geriatric patients for treatment of AAD are shown in Table 3.

Table 3: Adverse Events in ≥2 of REXULTI-Treated Patients and Greater than Placebo in Pooled 12-Week Placebo-Controlled, Clinical Studies.

Selected Adverse Events

Extrapyramidal Symptoms

Schizophrenia

In Trials 1 and 2, the incidence of EPS-related events, excluding akathisia events, was 5.1% for REXULTI-treated subjects versus 3.5% for placebo-treated subjects. The incidence of akathisia events (akathisia, psychomotor hyperactivity) for REXULTI-treated subjects was 5.4% versus 4.9% for placebo-treated subjects. Akathisia was reported in all treatment arms and were more often during Weeks 1 through 3 and was mild to moderate in severity.

In Trials 1 and 2, data were objectively collected on the Simpson Angus Scale (SAS) for extrapyramidal symptoms (EPS), the Barnes Akathisia Rating Scale (BARS) for akathisia and the Abnormal Involuntary Movement Scale (AIMS) for dyskinesia. The mean changes from baseline at last visit for REXULTI-treated subjects for the SAS, BARS and AIMS were comparable to those for placebo-treated subjects (-0.10, 0.02 and -0.08 compared to 0.00, 0.01 and -0.07 respectively).

Similarly, in Trial 3, the mean changes from baseline at last visit for REXULTI-treated subjects for the SAS, BARS and AIMS were comparable to those for the placebo-treated subjects.

Agitation Associated with Alzheimer's Dementia

The incidence of reported EPS-related adverse reactions in the 12-week placebo-controlled clinical studies in AAD (including akathisia) was (35/655) 5.3% for REXULTI-treated patients versus (12/388) 3.1% for placebo-treated patients. The incidence of akathisia events for REXULTI-treated patients was (12/655) 1.8% versus (1/388) 0.3% for placebo-treated patients.

In the 12-week placebo-controlled, clinical studies in AAD, data was objectively collected on the Simpson-Angus Rating Scale (SAS) for EPS, the Barnes Akathisia Rating Scale (BARS) for akathisia and the Abnormal Involuntary Movement Scale (AIMS) for dyskinesia. The mean change from baseline at last visit for REXULTI-treated patients for the SAS, BARS and AIMS was comparable to placebo-treated patients. The percentage of patients who shifted from normal to abnormal was greater in REXULTI-treated patients versus placebo for the SAS, 5.6% (36/638) versus 2.1% (8/378).

Dyslipidaemia

Undesirable alterations in lipids have been observed in subjects treated with atypical antipsychotics.

Schizophrenia

In Trials 1 and 2, changes in fasting total cholesterol, LDL cholesterol, and HDL cholesterol were similar in REXULTI- and placebo-treated subjects. Table 4 shows the proportions of subjects with changes in fasting triglycerides.

Table 4: Change in Fasting Triglycerides in Trials 1 and 2

Proportion of Subjects with Shifts Baseline to Post-Baseline					
	Placebo	1 mg/day	2 mg/day	4 mg/day	
Triglycerides <i>Normal to High</i> (<8.3 mmol/L to ≥11.1 and <27.8 mmol/L)	6%	10%	8%	10%	
	(15/253)*	(7/72)*	(19/232)*	(22/226)*	
Normal/Borderline to Very High (<11.1 mmol/L to ≥27.8 mmol/L)	0%	0%	0%	0.4%	
	(0/303)*	(0/94)*	(0/283)*	(1/283)*	

^{*} denotes n/N where N=the total number of subjects who had a measurement at baseline and at least one post-baseline result. n=the number of subjects with a shift.

In Trial 3, no clinically meaningful differences between treatment groups were observed for the incidences of metabolic parameters meeting potentially clinically relevant criteria.

In the long-term open-label studies, the mean change from baseline to last visit in fasting triglycerides was -0.11 mmol/L (N=1123).

Agitation Associated with Alzheimer's Disease

In the 12-week placebo-controlled, fixed-dose clinical studies in patients (51 to 90 years of age) with AAD, changes in total cholesterol, LDL cholesterol, and HDL cholesterol were similar in patients treated with REXULTI and patients treated with placebo. Changes seen in fasting triglycerides from normal/borderline (<11.1 mmol/L) to very high (≥27.8 mmol/L) were similar in patients treated with REXULTI and patients treated with placebo.

Mean values in lipid were similar in each treatment group at baseline. Regarding lipids the active extension trial showed lipid changes were noted with 4/116 (3.4%) participants who had total cholesterol <11.1mmol/L at baseline developed a change to high fasting total cholesterol (>13.3mmol/L) during trial (4% prior brexpiprazole vs 2.4% prior placebo). 6/92 (6.5%) of participants in prior brexpiprazole group with triglyceride levels <8.3mmol developed high (>11.1mmol/L) triglyceride levels post baseline compared to 1/57 (1.98%) in prior placebo.

11/173 (6.4%) participants who had HDL cholesterol ≥2.2mmol/L at baseline developed a change to low fasting HDL cholesterol (≤2.2mmol/L) during trial (8.6% prior brexpiprazole vs 2.9% prior placebo).

Weight Gain

Schizophrenia

The percentage of subjects in short-term Trials 1 and 2 who had a potentially clinically relevant increase in body weight (≥7%) was 10.5% and 10.2% in the REXULTI 2 and 4 mg/day groups, respectively, compared with 4.1% in the placebo group. The mean body weight increase in the short-term trials at last visit was 1.2 kg for both the REXULTI 2 and 4 mg/day groups compared with 0.2 kg in the placebo group.

During Trial 3 the proportion of subjects with a \geq 7% increase in body weight at last visit was 3.1 % in the REXULTI group compared to 1.0% in the placebo group.

In the long-term, open-label schizophrenia studies, the mean change in body weight from baseline to last visit was 1.1 kg at last observation.

Agitation Associated with Alzheimer's Dementia

In the 12-week placebo-controlled, fixed-dose and flexible-dose clinical studies in patients (51 to 90 years of age) with AAD, the mean changes in body weight from baseline to the last visit were similar in patients treated with REXULTI and patients treated with placebo. The proportion of the patients with a \geq 7% increase in body weight (kg) at any visit were 11/649 (1.7%) in REXULTI compared to 3/382 (0.8%) in the placebo group.

In patients (55 to 90 years of age) from the 12-week placebo-controlled, fixed-dose clinical study who rolled over into a 12-week, active-treatment extension study, 3/153 (2%) demonstrated a \geq 7% increase in body weight, and 4/92 (4.3%) demonstrated a \geq 7% decrease in body weight from baseline (start of the extension study) to last visit. In the open-label extension study, of the 259 patients treated, 87 participants had a normal BMI (>18.5 and <25) at baseline, 6/87 (6.9%) had an increase of \geq 7% in body weight, 2/54 (3.7%) in prior brexpiprazole group and 4/33 (12.1%) in the prior placebo group.

Post-Marketing Adverse Drug Reactions

Post-marketing reports of impulse-control disorders (including gambling), and also sleep walking and related behaviours (including sleep related eating disorder) have been reported very rarely with antipsychotics, including REXULTI. While causality has not been established, Lundbeck Australia Pty Ltd will continue to monitor the situation closely.

The following adverse reaction has been reported during the post-marketing period with REXULTI. The frequency of the reported adverse reaction is unknown.

Nervous System disorders: Neuroleptic malignant syndrome

Reporting suspected adverse effects

Reporting suspected adverse reactions after registration of the medicinal product is important. It allows continued monitoring of the benefit-risk balance of the medicinal product. Healthcare professionals are asked to report any suspected adverse reactions at www.tga.gov.au/reporting-problems.

4.9 Overdose

No specific information is available on the treatment of overdose with REXULTI. Gastric lavage and treatment with an emetic may be useful immediately after overdose. An electrocardiogram should be obtained in case of overdosage and if QT interval prolongation is present, cardiac monitoring should be instituted. Otherwise, management of overdose should concentrate on supportive therapy, maintaining an adequate airway, oxygenation and ventilation, and management of symptoms. Close medical supervision and monitoring should continue until the patient recovers.

For information on the management of overdose, contact the Poison Information Centre (Tel: 13 11 26 for Australia).

Oral activated charcoal and sorbitol (50 g/240 mL), administered one hour after ingesting oral REXULTI, decreased brexpiprazole C_{max} and AUC by approximately 5% to 23% and 31% to 39% respectively; however, there is insufficient information available on the therapeutic potential of activated charcoal in treating an overdose with REXULTI. Although there is no information on the effect of haemodialysis in treating an overdose with REXULTI, haemodialysis is unlikely to be useful in overdose management since brexpiprazole is highly bound to plasma proteins.

5 PHARMACOLOGICAL PROPERTIES

5.1 Pharmacodynamic properties

Brexpiprazole has high affinity (K_i <5 nM) for multiple monoaminergic receptors, including serotonin 5-HT_{1A}, 5-HT_{2A}, 5-HT_{2B} and 5-HT₇, dopamine D₂ and D₃, and noradrenergic α_{1A} , α_{1B} , α_{1D} , and α_{2C} receptors. Brexpiprazole acts as a partial agonist at 5-HT_{1A}, D₂, and D₃ receptors and as an antagonist at 5-HT_{2A}, 5-HT_{2B}, 5-HT₇, α_{1A} , α_{1B} , α_{1D} , and α_{2C} receptors. Brexpiprazole exhibits moderate affinity for histamine H₁ receptors (19 nM) and very weak affinity for muscarinic M₁ receptors (67% inhibition at 10 μ M). Dose-response occupancy and brain/plasma exposure relationship were determined *in vivo* or *ex vivo* for D₂/D₃, 5-HT_{2A}, 5-HT_{1A}, 5-HT₆, and 5-HT₇ receptors as well as for the 5-HT transporter in preclinical studies. These results are consistent with the relative *in vitro* binding affinities and indicate that brexpiprazole has potent activity at several targets in the central nervous system (CNS) at relevant plasma exposures.

Despite low intrinsic activity at D_2 receptors and potent antipsychotic effect, brexpiprazole showed low liability for catalepsy (animal model for extrapyramidal side effects) and for inducing tardive dyskinesia (indicative of increased sensitivity of the post-synaptic D_2 receptors). The potencies of these effects were similar to or lower than those of other antipsychotic agents. Brexpiprazole showed a relatively low binding affinity for H_1 receptors compared with that for D_2 receptors, implying a low potential for H_1 receptor-related sedative effects.

In a thorough QTc study in patients with schizophrenia or schizoaffective disorder, REXULTI did not prolong QTcI or QTcF after 12 days dosing at the clinical (4 mg/day) or at a supra-therapeutic (12 mg/day) dose, and no correlation was observed between brexpiprazole concentrations and QTcI or QTcF prolongation. Based on *in vitro* data the risk of hERG channel-mediated effects at the clinical dose appears to be low. There are no data on the potential for QTc prolongation via effects on the I_{Ks} (KCNQ1-KCNE1 complex) and Na_v (SCN5A) ion currents.

Mechanism of action

REXULTI is a novel atypical antipsychotic agent, which has pharmacological activity as a serotonin-dopamine activity modulator. While the precise mechanism of action of brexpiprazole in treating schizophrenia or agitation associated with Alzheimer's dementia is not fully understood, the pharmacology of brexpiprazole is believed to be mediated by a combination of high binding affinity and functional activities at multiple monoaminergic receptors. It has modulatory activity at the serotonin and dopamine systems that combines partial agonist activity at serotonergic 5-HT_{1A} and at dopaminergic D₂ receptors with antagonist activity at serotonergic 5-HT_{2A} receptors, with similar high affinities at all of these receptors (Ki: 0.1-0.5 nM). Brexpiprazole also shows antagonist activity at noradrenergic α 1B/2C receptors with affinity in the same sub-nanomolar Ki range (Ki: 0.2-0.6 nM). The 5-HT_{1A/D2} receptor partial agonist activity in combination with the 5-HT_{2A} and α 1B/2C receptor antagonism of brexpiprazole may contribute to its antipsychotic effect.

Clinical trials Schizophrenia

The efficacy of REXULTI in the treatment of adults with schizophrenia was demonstrated in two 6-week, randomised, double-blind, placebo-controlled, fixed-dose clinical trials (Trials 1 and 2) and one long-term maintenance trial (Trial 3) in subjects who met DSM-IV-TR criteria for schizophrenia.

In the two fixed-dose trials, subjects were randomised to REXULTI 2 mg once daily, 4 mg once daily or placebo. Subjects in the REXULTI groups initiated treatment at 1 mg once daily on Day 1. The REXULTI dosage was increased to 2 mg once daily on Day 5. On Day 8, the dosage was either maintained at 2 mg once daily or increased to 4 mg once daily, depending on treatment assignment, for the 5 remaining weeks. Trials 1 and 2 also included a low dose group, 0.25 mg/day and 1 mg/day REXULTI, respectively, but these dose groups were not included in the primary analysis.

The primary efficacy endpoint for both trials was the change from baseline to Week 6 in the Positive and Negative Syndrome Scale (PANSS) total score. The PANSS is a 30-item scale that measures positive symptoms of schizophrenia (7 items), negative symptoms of schizophrenia (7 items), and general psychopathology (16 items), each rated on a scale of 1 (absent) to 7 (extreme); the total PANSS scores range from 30 (best) to 210 (worst). The key secondary endpoint of both trials was the change from baseline to Week 6 in Clinical Global Impression – Severity of Illness Scale (CGI-S) score, a validated clinician-rated scale that measures the subject's current illness state and overall clinical state on a 1- (normal, not

at all ill) to 7-point (extremely ill) scale. Other secondary endpoints included the Personal and Social Performance scale (PSP), a validated clinician-rated scale that measures personal and social functioning.

In Trials 1 and 2, REXULTI 2 mg/day and 4 mg/day demonstrated efficacy with clinically meaningful changes in several efficacy endpoint measures.

At endpoint, REXULTI 4 mg was consistently superior to placebo in both fixed-dose trials, reducing disease symptoms and severity as assessed using the primary endpoint, the PANSS total score. The onset of action with REXULTI occurred as early as Week 1. In Trial 1, a significant improvement was achieved in PANSS total score by Week 1 for 2 mg/day (p=0.0139) and Week 2 for 4 mg/day (p=0.0009). In Trial 2, a significant improvement was achieved in PANSS total score by Week 1 and then from Week 3 onwards with 4 mg/day (p<0.05).

Results for the primary efficacy endpoint for Trials 1 and 2 are shown in Table 5.

Figure 1 shows the time course of response based on the primary efficacy measure (PANSS) in Trial 1.

Examination of population subgroups based on age, sex and race did not show any statistical evidence of differential responsiveness.

Table 5: Primary Efficacy Results for 6-Week Trials in Schizophrenia (Trials 1 and 2)

			Primary Efficacy Measure: PANSS				
Trial	Treatment Group	N	Mean Baseline Score (SD)	LS Mean Change from Baseline (SE)	LS Means Difference ^a (95% CI)	p-value	
1	REXULTI (2 mg/day)*	180	95.85 (13.75)	-20.73 (1.55)	-8.7 (-13.1, -4.4)	<.0001

SD: standard deviation; SE: standard error; LS Mean: least-squares mean; CI: unadjusted confidence interval.

^{*} Treatment statistically significantly superior to placebo

^a Difference (drug minus placebo) in least-squares mean change from baseline, at Week 6.

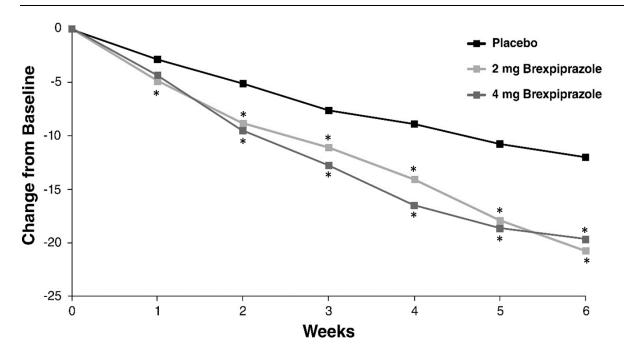

Figure 1: Change from Baseline in PANSS Total Score by Trial Visit (Week) - Trial 1

In addition, REXULTI 2 mg/day and 4 mg/day demonstrated superiority to placebo in the key secondary endpoint, CGI-S score. Significant improvements in CGI-S score were seen as early as Week 2 in Trial 1 and Week 3 in Trial 2.

In Trial 1, REXULTI also demonstrated superiority to placebo across several pre-specified secondary endpoints, including: the change from baseline to Week 6 in PSP score (2 mg/day), PANSS Positive Subscale score (2 mg/day and 4 mg/day) and PANSS Negative Subscale score (2 mg/day and 4 mg/day,); Clinical Global Impression - Improvement scale (CGI-I) score (2 mg/day and 4 mg/day); response rate at Week 6 (2 mg/day and 4 mg/day); and discontinuation for lack of efficacy (4 mg/day).

In Trial 2, REXULTI 4 mg/day demonstrated superiority to placebo in the change from baseline to Week 6 in PSP score, PANSS Positive Subscale score and PANSS Negative Subscale score; CGI-I score; response rate at Week 6.

Thus, the secondary endpoint results for CGI-S, PSP, CGI-I, PANSS Positive Subscale, PANSS Negative Subscale and response rate support the superiority and clinically meaningful effect of REXULTI compared to placebo.

Additionally, both trials had high overall completion rates, which were higher in the REXULTI groups than in the placebo group.

Results for the secondary efficacy endpoints for Trials 1 and 2 are shown in Table 6.

Table 6: Secondary Efficacy Results for 6-Week Trials in Schizophrenia (Trials 1 and 2)

		Trial 1	Trial 2		
Secondary Efficacy Endpoint	REXULTI 2 mg (N=180)	REXULTI 4 mg (N=178)	REXULTI 2 mg (N=179)	REXULTI 4 mg (N=181)	
CGI-S score, LSMD ^a (p-value)	-0.33 (0.0056)	-0.38 (0.0012)	-0.19 (0.1269)	-0.38 (0.0015)	
PSP score, LSMD ^a (p-value)	2.89 (0.0250)	2.46 (0.0557)	2.00 (0.1286)	4.59 (0.0005)	
PANSS Positive score, LSMD ^a (p-value)	-2.22 (0.0029)	-2.44 (0.0010)	-0.47 (0.5101)	-1.70 (0.0166)	
PANSS Negative score, LSMD ^a (p-value)	-1.78 (0.0007)	-1.41 (0.0069)	-0.77 (0.1547)	-1.22 (0.0231)	
CGI-I score, Mean Difference ^b (p-value)	-0.54 (0.0002)	-0.50 (0.0004)	-0.30 (0.0422)	-0.49 (0.0009)	
Response ^c Rate					
% Responders REXULTI	47.78%	46.07%	38.55%	49.72%	
Placebo	30	0.34 %	31.6	57%	
Relative Risk ^d (p-value)	1.59 (0.0004)	1.48 (0.0032)	1.22 (0.1680)	1.54 (0.0006)	

^a Difference (drug minus placebo) in least-squares mean change from baseline at Week 6.

The long-term trial (Trial 3) was a randomised, double-blind, placebo-controlled trial to assess the efficacy, safety, and tolerability of REXULTI 1 - 4 mg/day as maintenance treatment in adults with schizophrenia. The primary endpoint was the time to impending relapse. The key secondary endpoint was the percentage of subjects with impending relapse, and other secondary endpoints included the mean change in PANSS total score and CGI-S score.

A pre-specified interim analysis demonstrated a statistically significantly longer time to impending relapse in subjects randomised to the REXULTI group (1 - 4 mg/day) compared to subjects randomised to the placebo group (p = 0.0008, log-rank test) and the trial was subsequently terminated early because maintenance of efficacy was demonstrated. The final analysis also demonstrated a statistically significantly longer time to impending relapse in subjects randomised to the REXULTI group compared to subjects randomised to the placebo group (p < 0.0001, log-rank test). The Kaplan-Meier curves of the cumulative proportion of subjects who relapsed during the double-blind treatment phase for the REXULTI and placebo groups in the final analysis set are shown in Figure 2. For the final analysis, the hazard ratio from the Cox proportional hazard model for the placebo to REXULTI comparison was 3.42 (95% CI: 1.82, 6.41); thus, subjects in the placebo group had a 3.42-fold greater risk of experiencing impending relapse than the subjects in the REXULTI group.

^b Derived from the Cochran-Mantel-Haenszel (CMH) row mean score test.

^c Defined as a ≥30% reduction from baseline in PANSS total score or a CGI-I score of 1 or 2, using LOCF at Week 6.

^d Derived from the CMH general association test, stratified by trial site.

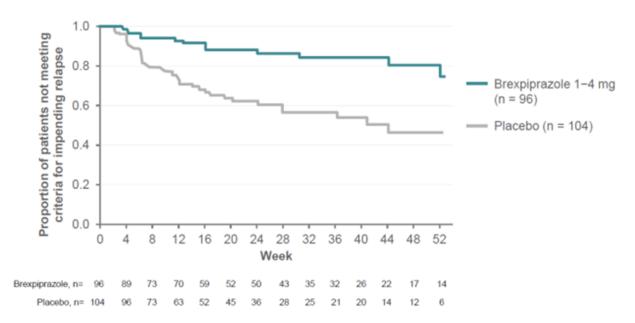

Figure 2: Kaplan-Meier Curves of Time to Impending Relapse (Double-blind Maintenance Phase Efficacy Sample) – Final Analysis, Trial 3

The key secondary endpoint, the proportion of subjects who met the criteria for impending relapse, was statistically significantly lower with the REXULTI group compared with the placebo group in both the interim and final analyses (15.38% vs 37.08%, p = 0.0016 and 13.54% vs 38.46%, p < 0.0001, respectively).

In the double-blind maintenance phase, the PANSS Total score and CGI-S score both showed supportive patterns of stability of symptoms, which were maintained over time with REXULTI treatment, whereas they worsened with placebo treatment (p = 0.0011, p = 0.0006, for the comparison of REXULTI vs placebo for PANSS total score and CGI-S, respectively).

Agitation Associated with Alzheimer's Dementia (AAD)

The efficacy of REXULTI in the treatment of agitation associated with Alzheimer's dementia (AAD) was demonstrated in two 12-week, randomized, double-blind, placebo-controlled, fixed dose studies (Trial 4, NCT01862640 and Trial 5, NCT03548584) who met a diagnosis of probable Alzheimer's Disease according to NINCDS-ADRDA criteria and a Mini-Mental State Examination (MMSE) score of \geq 5 and \leq 22. At entry, patients were required to have a total score of \geq 4 on the agitation/aggression item of the NPI/NPI-NH. Patients were required to be exhibiting sufficient agitation behaviours at time of entry to warrant use of pharmacotherapy, after excluding other factors.

Enriched sample. Patients in Trial 5 had to meet additional inclusion criteria, referring to the provisional consensus definition of the International Psychogeriatric Association (IPA) for agitation in patients with cognitive disorders (2014). Subjects also had to meet predetermined blinded eligibility criteria referring to CMAI Factor 1 (aggressive behaviour) at baseline. In order to meet this criterion, one of the following must be displayed: ≥ 1 aggressive behaviours occurring several times per week, or ≥ 2 aggressive behaviours occurring once or twice per week, or ≥ 3 aggressive behaviours occurring less than once per week. Aggressive

behaviours refer to hitting (including self), kicking, scratching, grabbing, pushing, hurting self or others, throwing things, cursing or verbal aggression, spitting, tearing things or destroying property, screaming and biting.

AAD patients who had not responded to at least two antipsychotics in the past were excluded from the REXULTI clinical development program.

Trial 4 included 433 patients with a mean age of 74 years, and a range of 51 and 90 years. Trial 5 included 345 patients with a mean age of 74 years, and a range of 56 and 90 years.

The primary efficacy endpoint in all studies was the change from baseline in the Cohen-Mansfield Agitation Inventory (CMAI) score at Week 12. The CMAI is a clinician rated questionnaire consisting of 29 items, which assess the frequency of manifestations of agitated behaviours in elderly patients, based on caregiver input. Three specific factors can be derived from the CMAI scale: 1) Aggressive Behaviour (e.g., screaming, throwing things, cursing/verbal aggression, kicking, pushing scratching, hurting self or others); 2) Physically Non-Aggressive Behaviour (e.g., repetitive mannerisms, general restlessness, pacing); and 3) Verbally Agitated Behaviour (e.g., complaining, repetitive questions, constant requests for attention). Each CMAI behaviour was rated on a scale of 1 (never) to 7 (very frequent agitated behaviours); the total CMAI scores range from 29 (best) to 203 (worst). A negative change in score indicates improvement.

Patients in Trial 4 were randomized to a fixed dose of either REXULTI 1 mg once a day, 2 mg once a day or placebo. In this trial, patients who received REXULTI 2 mg once daily showed improved CMAI scores compared to patients who received placebo at Week 12. Patients in Trial 5 were randomized to a fixed dose of either REXULTI 2 mg or 3 mg once a day (combined treatment arm) or placebo. In this trial, patients who received REXULTI 2 mg or 3 mg once daily showed improved CMAI scores compared to patients who received placebo at Week 12.

As shown in Table 7

and Figure 3, the mean change from baseline in the CMAI score after 12 weeks in patients treated with 2 mg per day or 3 mg per day of REXULTI was statistically significantly superior to placebo. The once daily 1 mg dose did not demonstrate significantly greater mean changes at baseline from placebo in the CMAI score in this patient population.

Table 7: Change in CMAI Total Score* from Baseline at Week 12 in Patients with Agitation Associated with Alzheimer's Dementia in Trial 4 and Trial 5

Trial	Treatment Group	N	Mean Baseline Score (SD)	LS Mean Change (SE)	Treatment Difference [‡] (95% CI)
	REXULTI 1 mg/day	134	70.5 (16.0)	-17.6 (1.3)	0.2 (-3.4, 3.9)
4	REXULTI 2 mg/day [†]	138	71.0 (16.6)	-21.6 (1.3)	-3.8 (-7.4, -0.2)
	Placebo	131	72.2 (17.9)	-17.8 (1.3)	_
5	REXULTI 2 mg/day or 3 mg/day [†]	225	80.6 (16.6)	-22.6 (1.1)	-5.3 (-8.8, -1.9)
	Placebo	116	79.2 (17.5)	-17.3 (1.4)	_

SD: standard deviation; SE: standard error; LS Mean: least-square mean; CI: unadjusted confidence interval

Examination of population subsets (age, race, and gender) on the primary endpoint did not reveal any differential responsiveness on the basis of these subgroupings.

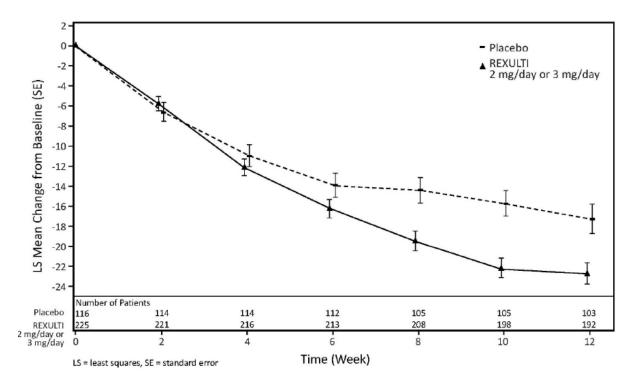

Figure 3: Change in CMAI Total Score from Baseline by Study Week in Patients with Agitation Associated with Alzheimer's Dementia from Trial 5

5.2 Pharmacokinetic properties

Absorption

Brexpiprazole is well absorbed after administration of REXULTI tablets, with peak plasma concentrations occurring within 4.0 hours after single-dose administration; the absolute oral bioavailability of the tablet formulation is 95.1%. Brexpiprazole steady-state concentrations are attained within 10-12 days of dosing. REXULTI can be administered with or without

[†]Difference (drug minus placebo) in least-squares mean change from baseline

[†]Dosages statistically significantly superior to placebo

food. Administration of a REXULTI 4 mg tablet with a standard high-fat meal did not significantly affect the C_{max} or AUC of brexpiprazole. After single and multiple once-daily dose administration, brexpiprazole exposure (C_{max} and AUC) increased in proportion to the dose administered. *In vitro* studies did not indicate that brexpiprazole is a substrate of efflux transporters such as MDRI (P-gp) and BCRP.

Distribution

The volume of distribution of brexpiprazole following intravenous administration is high (1.56±0.418 L/kg), indicating extravascular distribution. Brexpiprazole is highly protein bound in plasma (greater than 99%) to serum albumin and α1-acid glycoprotein, and its protein binding is not affected by renal or hepatic impairment. Based on results of *in vitro* studies, brexpiprazole protein binding is not affected by warfarin, diazepam, or digoxin.

Metabolism and Excretion

Based on *in vitro* metabolism studies of brexpiprazole using recombinant human cytochrome P450 (CYP1A1, 1A2, 2A6, 2B6, 2C8, 2C9, 2C19, 2D6, 2E1 and 3A4), the metabolism of brexpiprazole was shown to be mainly mediated by CYP3A4 and CYP2D6. Based on the results of *in vitro* data, brexpiprazole showed little to no inhibition of CYP450 isozymes. The *in vitro* inhibitory potential of brexpiprazole on MDR1 (P-gp), OAT1, OAT3, OCT2, multidrug and toxin extruders (MATE1), MATE2-K, OATP1B1, OATP1B3, and OCT1 has also been evaluated; brexpiprazole was only identified as a potential inhibitor of the BCRP efflux transporter, but was not considered to be an inhibitor of the other tested transporters.

In vivo, brexpiprazole is metabolised primarily by CYP3A4 and CYP2D6 enzymes. After single- and multiple-dose administrations, brexpiprazole and a major metabolite, DM-3411, are the predominant drug moieties in the systemic circulation. At steady-state, DM-3411 represents 23.1-47.7% of brexpiprazole exposure (AUC) in plasma. It should be noted that *in vivo* preclinical studies have shown that at clinically relevant plasma exposures of brexpiprazole, DM-3411 brain exposures were below the detection limit. Thus, DM-3411 is considered not to contribute to the therapeutic effects of brexpiprazole.

Following a single oral dose of [¹⁴C]-labelled brexpiprazole, approximately 24.6% and 46% of the administered radioactivity was recovered in the urine and faeces, respectively. Less than 1% of unchanged brexpiprazole was excreted in the urine and approximately 14% of the oral dose was recovered unchanged in the faeces. The apparent oral clearance of brexpiprazole after once-daily tablet administration is 19.8 (±11.4) mL/h/kg. After multiple once-daily administrations of REXULTI, the terminal elimination half-life of brexpiprazole and its major metabolite, DM-3411, is 91.4 hours and 85.7 hours, respectively.

Special Populations

Age/Sex

After single-dose administration of REXULTI (2 mg), healthy elderly subjects (older than 65 years old) exhibited similar brexpiprazole systemic exposure (C_{max} and AUC) in comparison with adult subjects (18-45 years old) and female subjects exhibited approximately 40-50% higher brexpiprazole systemic exposure (C_{max} and AUC) in

comparison with male subjects. Population pharmacokinetic evaluation identified age and female sex as statistically significant covariates affecting brexpiprazole pharmacokinetics and not considered clinically relevant.

Race

Although no specific pharmacokinetic study was conducted to investigate the effects of race on the disposition of brexpiprazole, population pharmacokinetic evaluation revealed no evidence of clinically significant race-related differences in the pharmacokinetics of brexpiprazole.

CYP2D6 Poor Metabolisers

Approximately 8% of Caucasians and 3–8% of Blacks/African Americans lack the capacity to metabolise CYP2D6 substrates and are classified as PM, whereas the rest are EM. Population pharmacokinetic evaluation shows that CYP2D6 PMs have 47% higher exposure to brexpiprazole compared to EMs. (See Section 4.2 Dose and method of administration)

Smoking

Based on studies utilising human liver enzymes *in vitro*, brexpiprazole is not a substrate for CYP1A2. Smoking should, therefore, not have an effect on the pharmacokinetics of brexpiprazole.

Hepatic Impairment

Patients with moderate to severe hepatic impairment (Child-Pugh score ≥7) generally had higher exposure to brexpiprazole than patients with normal hepatic function; therefore, the recommended maximum dose should be reduced. In subjects with varying degrees of hepatic impairment (Child-Pugh Classes A, B, and C), the AUC of oral brexpiprazole (2 mg single dose), compared to matched healthy subjects, increased 24% in mild hepatic impairment, increased 60% in moderate hepatic impairment, and did not change in severe hepatic impairment.

Renal Impairment

Patients with impaired renal function (CLcr <60 mL/minute) had higher exposure to brexpiprazole than patients with normal renal function; therefore, the recommended maximum dose should be reduced. In subjects with severe renal impairment (CL $_{cr}$ <30 mL/min), the AUC of oral brexpiprazole (2 mg single dose) compared to matched healthy subjects, increased 68% while its C_{max} did not change.

5.3 Preclinical safety data

Genotoxicity

The mutagenic potential of brexpiprazole was tested in the *in vitro* bacterial reverse mutation assay, the *in vitro* forward gene mutation assay in mouse lymphoma cells, the *in vitro* chromosomal aberration assay in Chinese hamster ovary (CHO) cells, the *in vivo* micronucleus assay in rats, and the unscheduled DNA synthesis assay in rats. Brexpiprazole was mutagenic and induced chromosomal aberrations in mammalian cells *in vitro* but only at cytotoxic concentrations. No mutagenicity or genotoxicity was observed in the higher tier

in vivo studies. Brexpiprazole is unlikely to affect the mitotic spindle or kinetochores. Based on the weight of evidence, brexpiprazole is not considered to present a genotoxic risk to humans.

Carcinogenicity

The lifetime carcinogenic potential of brexpiprazole was evaluated in two-year oral (gavage) studies in ICR mice and Sprague-Dawley rats. Brexpiprazole was administered to mice at doses of 0.75, 2 and 5 mg/kg/day, with plasma AUC exposures of 0.4-4-fold (males) and 0.2-1-fold (females) clinical exposure at the 4 mg/day MRHD. There was no increase in the incidence of tumours in males at any dose group. In female mice, there was an increased incidence of mammary gland adenocarcinoma and adenosquamous carcinoma, and pars distalis adenoma of the pituitary gland, at all doses. Brexpiprazole was administered to rats at doses of 1, 3 and 10 mg/kg/day (males) or 3, 10 and 30 mg/kg/day (females), with plasma AUC exposure up to 1-fold (males) and 6-fold (females) clinical exposure at the 4 mg/day MRHD. Long-term administration of brexpiprazole to rats did not induce neoplastic lesions.

Proliferative and/or neoplastic changes in the mammary and pituitary glands of rodents have been observed following chronic administration of antipsychotic drugs and are considered to be secondary to D₂-antagonist-induced hyperprolactinaemia. The potential for increasing serum prolactin level of brexpiprazole was shown in both mice and rats. The relevance for human risk of the findings of prolactin-mediated endocrine tumors in rodents is unknown.

6 PHARMACEUTICAL PARTICULARS

6.1 List of excipients

REXULTI tablets contain the following inactive ingredients: lactose monohydrate, maize starch, microcrystalline cellulose, hyprolose and magnesium stearate.

The OPADRY complete coating systems are used in REXULTI:

- 0.25 mg tablets OPADRY complete film coating system 03A465005 BROWN (ID 110573);
- 0.5 mg tablets OPADRY complete film coating system 03A430000 ORANGE (ID 110574);
- 1 mg tablets OPADRY complete film coating system 03A420002 YELLOW (ID 110572);
- 2 mg tablets OPADRY complete film coating system 03A410000 GREEN (ID 110570);
- 3 mg tablets OPADRY complete film coating system 03A400000 PURPLE (ID 110575) and
- 4 mg tablets OPADRY complete film coating system 03A480004 WHITE (ID 110571).

6.2 Incompatibilities

Refer to Section 4.5 – Interactions with other medicines and other forms of interactions.

6.3 Shelf life

In Australia, information on the shelf life can be found on the public summary of the Australian Register of Therapeutic Goods (ARTG). The expiry date can be found on the packaging.

6.4 Special precautions for storage

Store below 30°C.

6.5 Nature and contents of container

REXULTI tablets are packaged in polyvinyl chloride (PVC)/aluminium foil blisters.

Pack sizes of 30 film-coated tablets (all strengths). Starter pack size of 10 film-coated tablets: 1 mg and 2 mg.

6.6 Special precautions for disposal

In Australia, any unused medicine or waste material should be disposed of by taking to your local pharmacy.

6.7 Physicochemical properties

Brexpiprazole is 7-{4-[4-(1-benzothiophen-4-yl)piperazin-1-yl]butyloxy}quinolin-2(1*H*)-one.

Molecular formula: C₂₅H₂₇N₃O₂S

Molecular weight: 433.57

Brexpiprazole is nonhygroscopic, with white to off-white crystals or crystalline powders, and a melting point of 183°C (decomposition). It is practically insoluble in water, and the solubility of the drug substance is 0.56 mg/mL at pH 2.
